Temperaturextreme	7
Aufzeichnungen der autographischen Apparate für Luftdruck, Temperatur, Richtung und Geschwindigkeit des Windes auf den Stationen:	123—126
Zürich und Säntis 1926	55 Seiten

Anhang: Ergänzende Beobachtungen und Abhandlungen.

Nr. 1. Uebersicht über den Witterungsverlauf in der Schweiz im Jahre 1926	7 Seiten
Nr. 2. Ergebnisse der Niederschlagsmessungen im Jahre 1926; Die Niederschlagsbilanz des Jahres 1926; Ergebnisse der im Alpengebiete aufgestellten Totalisatoren pro 1925/26; Der Firnzuwachs pro 1925/26 in einigen Gletschergebieten der Schweizeralpen (Messungen der Gletscherkommission der Phys. Ges. Zürich)	22
Nr. 3. Gewitterbeobachtungen im Jahre 1926	48
Nr. 4. Ergebnisse der Registrierungen der Sonnenscheinantographen im Jahre 1926	4
Nr. 5. Jahresbericht des Erdbebendienstes der Schweiz im Jahre 1926	14

Einleitung.

Am 4. Juli 1926 verlor die Eidg. Meteorologische Kommission ihr sehr verdientes ältestes Mitglied, Prof. A. Forster, Bern. Die Anstalt wird ihrem treuen Gönner stets ein ehrendes Gedenken bewahren.

Im Berichtsjahr hat die Meteorologische Zentralanstalt die besondere Ehre gehabt, eine Reihe von Internationalen Kommissionen der verschiedenen Spezialgebiete ihrer Wissenschaft in Zürich empfangen zu dürfen. Sie tagten vom 13. bis 20. September in den Räumen der Forstlich-Landwirtschaftlichen Schule der Eidg. Techn. Hochschule und den Verhandlungen schloss sich unmittelbar nachher die Versammlung des Meteorologischen Komitees mit allen seinen Vertretern in Wien an (25. September bis 1. Oktober). In derselben Zeit feierte unsere Schwesteranstalt in Wien ihr 75jähriges Bestehen. An die Wiener Konferenz ordnete der h. Bundesrat den Direktor der Anstalt ab.

Die Zahl der Beobachtungsstationen hat sich im Jahre 1926 wiederum nicht nennenswert verändert; die Anstalt arbeitet zur Zeit mit 120 meteorologischen und 293 Regenmess-Stationen. Einen verdienten langjährigen Beobachter haben wir in der Person des in den Ruhestand getretenen Pfarrer Dr. Wilhelm Bühler in Winterlingen-Baselland verloren; mangels geeigneter Nachfolge ist die Station nicht weitergeführt worden.

Im Wetterdienst hat sich seit dem letztjährigen Bericht organisatorisch nicht viel geändert. Die auf Wunsch des Eidg. Luftamtes versuchsweise übernommene Beteiligung des Institutes am Wetterdienst für den Internationalen Flugverkehr wurde auch dieses Jahr — und zwar schon anfangs April — wieder aufgenommen und mit dem bescheidenen Personal bestmöglich durchgeführt. Eine Neuerung war die Einführung des Böenwarnungsdienstes, der indessen nach den gemachten Erfahrungen noch sehr der Verbesserung bedarf. — Die seit Anfang bestehende Schwierigkeit eines störungsfreien Empfangs der drahtlos eingehenden internationalen Witterungstelegramme, konnte endlich zufriedenstellend behoben werden durch Erstellung einer kleinen, praktisch eingerichteten Schaltstation im Walde auf der Höhe des Zürichbergs (zirka 640 m ü. M.). Die städtischen Behörden überliessen hiefür schenkungsweise den nötigen Platz. Die neue Schaltstation ist im Oktober bezogen worden und arbeitet nun unter Beiziehung der nötigen Radiotelegraphisten einwandfrei. Sie ist durch zwei Telephonleitungen direkt mit der Meteorologischen Zentralanstalt verbunden und alle Telegramme können im Radiolokal, wo sich der Wetterdienst der Anstalt befindet, ohne weitere Störung abgenommen werden.

Die hydrologische Sektion der Anstalt hat im Berichtsjahr ihr Arbeitsprogramm tatkräftig weitergeführt. An der Internationalen Ausstellung für Binnenschifffahrt und Wasserkraftnutzung in Basel beteiligte sie sich mit umfangreichem Material, das vor allem die Hydrologie des Hochgebirges betraf. Die im Vorjahre unter gefl. Mitwirkung der nordostschweizerischen Kraftwerke und des Elektrizitätswerkes der Stadt Zürich begonnenen Studien im Wäggitäl über Niederschlag und Abfluss wurden im Berichtsjahre fortgesetzt. In Verbindung mit der Abteilung für Elektrifikation der Schweizerischen Bundesbahnen gelangten ferner im Barberinegebiet (Wallis) für das Studium der Niederschlags- und Abfluss-Verhältnisse neun weitere Niederschlagssammler zur Aufstellung. Für die Erforschung des Niederschlagsregimes in den höchsten Lagen des Jungfraugebietes wurden am Trugberg noch zwei Niederschlagssammler günstig plaziert.

Der Jahresbericht des Erdbebendienstes ist den Annalen wie bisher als Nr. 5 des Anhanges beigelegt; er wurde auch diesmal verfasst im Auftrage der Direktion von Herrn Assistent Dr. Gassmann. Der Verdienste des viel zu früh verewigten Leiters unseres Schweiz. Erdbebendienstes, Prof. Alfred de Quervain, † anfangs 1927, wird im nächstjährigen Vorwort gebührend gedacht werden.

Zürich, im Dezember 1927.

Die Direktion der Schweizerischen Meteorologischen Zentralanstalt:

Dr. J. Maurer.

EIDGENÖSS. METEOROLOGISCHE KOMMISSION

1926.

Präsident:	Herr Prof. R. GAUTIER in Genf.

Tägliche Beobachtungen

der Stationen:

Bern, Neuchâtel, Altdorf, Genf, Zürich, Rigi-Kulm, Bevers, Sitten,
Lugano, Basel, Säntis und St. Gotthard
im Jahre 1926.

Für die Bezeichnung der Hydrometeore und anderer Phänomene werden nach dem Vorschlag des internationalen Meteorologen-Kongresses (Wien 1873) folgende Symbole angewandt:

● = Regen.	△ = Tau.	☉ = Gewitter.	⊙ = Sonnenhof.
* = Schnee.	⊖ = Reif.	⚡ = Blitz, Wetterleuchten.	⊕ = Sonnenring.
△ = Graupeln, Riesel.	∇ = Duft.	↖ = Nordlicht.	☾ = Mondhof.
▲ = Hagel.	☄ = Glatteis.	☄ = starker Wind, ☄ = Sturm.	☾ = Mondring.
← = Eisnadeln.	≡ = Nebel.	⚡ = Schneegestöber.	☾ = Regenbogen.

Das Zeichen ☒ bedeutet, dass mehr als die Hälfte der Bodenfläche in der Umgebung der Station an dem betreffenden Tag mit Schnee bedeckt war. Die Intensität der einzelnen Erscheinungen wird durch eine dem Symbol als Exponent beigefügte ° als schwach, durch * als stark bezeichnet.

In der Spalte „Witterung“ bedeuten die Abkürzungen: fl. = Flocken, fr. = früh, sch. = Schauer, tr. = Tropfen, T = Donner, m. U. = mit Unterbrechungen.

Vom Jahrgang 1918 an ist die 24-Stundenzählung durchgeführt; wenn die Zeit nicht näher angegeben werden kann, bedeutet wie bis anhin: a: Vormittags (ante meridiem), p: Nachmittags (post m.), n: Nachts.

Alle Zeitangaben mit Ausnahme derjenigen in Anhang Nr. 4 beziehen sich auf **mitteleuropäische Zeit**.

Die römischen Ziffern geben an, dass das betreffende Phänomen um die Zeit des ersten, resp. zweiten, resp. dritten Beobachtungstermins stattgefunden hat, die arabischen bedeuten die bürgerlichen Zeitstunden, das Zeichen * interpolierte Daten.

λ bezeichnet die geographische Länge in Graden von Greenwich, β die geographische Breite, H_b die Höhe des Stationsbarometers über dem Meer in Metern, H die Höhe der Station (des Regenmessers) über der Meeresfläche, G ist die Korrektion, welche an den Luftdruckdaten für deren Reduktion auf die Normalschwere (45° Breite und das Meeresniveau) noch anzubringen ist, h_r die Höhe des oberen Randes des Regenmessers über dem Erdboden. Die Stationen, bei denen die Höhe (des Barometergefässes) bis auf den Dezimeter angegeben ist, sind an das schweizerische Präzisionsnivelement angeschlossen. Alle Höhen sind auf Pierre du Niton 373.6^m bezogen.

Errata zum Jahrgang 1926.

Das Zeichen ☒ fehlt: Seite 7, **Neuchâtel** Febr. 1.-6.; Seite 9, **Rigi** 1.-28.; Seite 10, **Bevers** 1.-28., **Sitten** 1.-3.; Seite 12, **Säntis** u. **Gotthard** 1.-28.

Seite 27. **Rigi**, Luftdruck 16. Mai lies: 601.2, 602.1, 603.4.

„ 69. **Zürich**, Temperatur Tagesmittel 15. Dez. lies: 3.3.

„ 80. **Säntis**, Luftdruck, Min. Jahr lies: XI.

„ 87. **St. Gallen**, Zahl der Tage mit ☉ im Jahr lies: 163.

„ 99. **St. Beatenberg**, Beobachter, lies: K. Lindt, Fr. Rupp (seit 1. April).

Resultate der Aufzeichnungen der autographischen Apparate . . . Seite 30, Febr. 27. 7⁵⁰ lies: -2.7.

Anhang Nr. 2, Seite 19 lies: 3., 5. und 12. **September**. Von dem gleich dem **August** . . . ,

(desgleichen in den Ergebnissen der täglichen Niederschlagsmessungen Seite 234).

Monats- und Jahresübersichten sämtlicher schweiz. meteorologischen Stationen.

In die hier folgenden Uebersichten werden die Beobachtungsergebnisse aller schweizerischen Stationen, soweit es die Zuverlässigkeit und Vollständigkeit derselben gestattet, aufgenommen.

Das Schema ist dem vom ersten internationalen Meteorologenkongress aufgestellten möglichst angepasst.

Zu beachten ist:

1. Die Minima und Maxima bei Luftdruck, Temperatur und die Minima bei der relativen Feuchtigkeit sind stets den üblichen Terminbeobachtungen entnommen (7^{80} 13^{80} 21^{80} , resp. 7^{80} 13^{80} 20^{80} ; bei Genf 7^{88} 13^{88} 21^{88}).
2. Die Monatsmittel der Temperatur werden aus den 3 Terminbeobachtungen in der Weise abgeleitet, dass der Abendbeobachtung (21^{80}) das doppelte Gewicht beigelegt ist [$m = \frac{1}{4} (7^{80} + 13^{80} + 2 \cdot 21^{80})$]. Bei den wenigen Stationen, die eine andere Kombination der Beobachtungsstunden haben, wird die entsprechende Reduktion nach den stündlichen Werten von Bern und Säntis angebracht.
3. Zu den Tagen mit Niederschlag werden alle gezählt, an denen derselbe den Betrag von wenigstens 0.3^{mm} erreicht, sei dies nun Regen oder Schnee, oder beides zugleich.
Eine zweite Rubrik enthält die Zahl der Tage mit Niederschlagsmengen von mindestens 1.0^{mm} .
4. Tage mit mehreren Gewittern werden nur einfach gezählt.
5. Als heitere Tage werden solche bezeichnet, deren mittlere Bewölkung < 2 .
» trübe » » » » » » » > 8 .
6. Bei der Uebersicht der Windverteilung wird nur die Häufigkeit der verschiedenen Windrichtungen mit Intensität > 0 berücksichtigt.
7. λ bezeichnet die geographische Länge in Graden von Greenwich, β die geographische Breite, H_b die Höhe des Stationsbarometers über dem Meer in Metern, H die Höhe der Station (des Regenmessers) über der Meeresfläche, G ist die Korrektur, welche an den Luftdruckdaten für deren Reduktion auf die Normalschwere (45° Breite und das Meeresniveau) noch anzubringen ist, h_r die Höhe des oberen Randes des Regenmessers über dem Erdboden. Die Stationen, bei denen die Höhe (der Barometercuvette) bis auf den Dezimeter angegeben ist, sind an das schweizerische Präzisionsnivelement angeschlossen. Alle Höhen sind auf Pierre du Niton 373.6^m bezogen.

Zürich.

 $\lambda = 8^{\circ} 33', \beta = 47^{\circ} 23', H_b = 493.2^m, G = -0.08 \frac{m}{m}, h_r = 1.4^m$

**Resultate der Aufzeichnungen der autographischen Apparate
für Luftdruck, Temperatur, Richtung und Geschwindigkeit des Windes
auf den Stationen: Zürich und Säntis
im Jahre 1926.**

In den nachstehenden Tabellen folgen die stündlichen Werte einiger meteorologischen Elemente für Zürich und Säntis. — Auf beiden Stationen werden die Temperaturen durch Richard'sche Thermographen, die Aufzeichnungen der Windrichtung und Windgeschwindigkeit durch Anemographen von Beckley, in Zürich die Daten für Luftdruck durch einen Sprung-Fuess'schen, auf dem Säntis durch einen Richard'schen Barographen erhalten. Die Stundenzählung ist auch hier von 0—24 durchgeführt. — Die Drucklegung der Registrierungen von Bern wurde 1919 sistiert und unterbleibt bis auf weiteres.

Januar 1926.

Stündliche Lufttemperaturen.

$h_t^* = 1.8^m$.

Zürich.

Anhang

zum Jahrgang 1926 der

Annalen der schweizerischen meteorologischen Zentralanstalt.

Ergänzende Beobachtungen und

Abhandlungen.

Nr. 1.

Uebersicht über den Witterungsverlauf in der Schweiz im Jahre 1926

von Dr. W. Brückmann.

Das Jahr 1926 war für die Schweiz beiderseits der Alpen erheblich wärmer als normal. Die positiven Abweichungen des Temperaturmittels betragen $\frac{3}{4}$ — 1° ; die sehr warmen Jahre 1911 und 1921 sind damit nicht ganz erreicht worden.

Die Jahresmengen des Niederschlages weichen im Mittelland im ganzen nicht weit von den normalen ab. Die Berglagen, sowie der Süden des Landes dagegen haben sehr erhebliche Ueberschüsse zu verzeichnen, der Nordrand des Jura umgekehrt ein deutliches Defizit.

Die Bewölkungszahlen sind für die Südwest- und die Südschweiz kleiner ausgefallen, als dem langjährigen Durchschnitt entspricht, sonst fast überall etwas grösser.

Hinsichtlich der registrierten Sonnenscheindauer sind vor allem erhebliche Mehrbeträge im Gebiete des Genfersees, Fehlbeträge dagegen in der Südschweiz und besonders an den hoch gelegenen Stationen hervorzuheben.

Für die einzelnen Monate ergibt sich folgendes Witterungsbild:

Der **Januar** 1926 ist im Durchschnitt für den grössten Teil der Schweiz sehr milde gewesen und reicher an Niederschlägen, als normal. Das Monatsmittel der Temperatur weicht im Mittelland und Jura um rund $+1^{\circ}$ bis $+2^{\circ}$ vom langjährigen Wert ab; im Gegensatz dazu ist aber für die Gipfelstationen und für den Alpensüdfuss der Monat um $\frac{1}{2}$ — 1° zu kalt ausgefallen. Die Niederschlagsüberschüsse nehmen von Westen nach Osten hin ab, in Genf und Neuenburg betragen sie mehr als 80% der normalen Monatsmengen, in St. Gallen 30%, in Basel 10%. In Süd- und Südostschweiz wurden die mittleren Beträge oder leichte Defizite verzeichnet. Ungewöhnlich ergiebig waren die Niederschläge auf dem Rigi, wo das vierfache der mittleren Januarmenge gemessen worden ist. Die Bewölkung war für die höheren Lagen des eigentlichen Alpengebietes übnormal, sonst etwa dem Durchschnitt entsprechend oder leicht darunter. Die Sonnenscheinregistrierungen zeigen Fehlbeträge an den hochgelegenen, leichte Ueberschüsse an den tieferen Stationen.

Die Schweiz hatte in der ersten Woche des Januar unter der Einwirkung mehrerer von England zur Ostsee ziehender Minima bewölktes, mildes Wetter mit täglichen Niederschlägen. Am 8. begann eine nachhaltige Besserung

der Lage, der Luftdruck stieg zunächst im Südwesten Europas, an den folgenden Tagen rasch auch im Osten und Nordosten, so dass der Kontinent bald im Zeichen einer intensiven Antizyklone mit Kern über Russland stand. Die Schweiz erhielt trockenes und meist heiteres Bisenwetter bei stark erniedrigten Temperaturen. Jungfrauoch meldete am 13. — 32° , und auch die Südseite der Alpen wurde von den kalten Luftmassen erreicht (Lugano — 9° und Schneefall). Vom 14. an traten am Westrand des grossen Hochdruckgebietes, über Frankreich, kleinere Störungszentren auf, die langsam nordostwärts zogen und für uns von Schneefällen bei fortdauernd niedrigen Temperaturen begleitet waren. In den ersten beiden Tagen fielen die grössten Schneemengen im Tessin, das darnach heiteres aber weiter sehr kaltes Wetter erhielt. In der Nordschweiz war der Schneefall besonders stark in der Nacht zum 18.; der Frost liess hier dann allmählich nach. Mit dem 22. machte sich eine neue Druckverstärkung geltend, die Bewölkung wurde leichter und die Niederschläge hörten auf. Eine stärkere Störung, bei der es bis auf 1200 m Höhe hinauf regnete, setzte am 29. mit dem Vorübergang einer Tiefdruckrinne ein. Eine nachfolgende föhnige Aufheiterung war nur von kurzer Dauer, der 31. war von neuem trübe und regnerisch. Während der letzten Woche des Monats lagen die Temperaturen wieder allgemein beträchtlich hoch für die Jahreszeit.

Der **Februar** war für die Schweiz nördlich der Alpen der wärmste Februar seit 1867. Die Abweichungen der Temperaturmittel liegen im Gebiet des Genfersees etwas unter 4° , weiter ostwärts zwischen 4 und 5° , an einzelnen Stationen gehen sie bis $5\frac{1}{2}^{\circ}$. Auch für das Tessin war die positive Abweichung beträchtlich, wenn auch nicht so extrem, wie im übrigen Lande. Die mittlere Bewölkung ist im ganzen, besonders in den höheren Lagen, etwas grösser als normal ausgefallen. Die Sonnenscheindauer lag im Südwesten leicht über dem Durchschnitt, sonst ein wenig darunter. Die Niederschlagsmengen zeigen im Süden und im Südwesten, sowie auf den Gipfelstationen Ueberschüsse — Lugano um 140%, Genf um 90%, Rigi und Säntis um 40% —, sonst Defizite bis zu etwa 40% der normalen Beträge.

Bei zunehmender zyklonaler Tätigkeit vom Atlantik her und gleichzeitig hohem Luftdruck im Osten und Süden Europas war der Anfang des Februar bei uns trübe und

leicht regnerisch. In den Alpentälern der Nordseite setzte kräftiger Föhn ein, und das Tessin erhielt reichlichen Regen. Diese Lage fand am 3. ihren Abschluss durch den mit böenartigen Erscheinungen erfolgenden Vorübergang einer Teildepression, die der Westschweiz stärkere Regenfälle brachte als dem Osten. An den folgenden Tagen hatte unser Land, nach Verstärkung des Luftdruckes, im ganzen leichtere Bewölkung, vom 7.—12. dann wieder, unter dem Regime eines flachen, Westeuropa überlagernden Minimums vorwiegend bedecktes und trübes Wetter mit Niederschlägen, die im Süden und Südwesten zeitweise erheblich, sonst gering waren. Am 13. zeigt das Bild der Isobaren eine Ausbreitung der russischen Antizyklone gegen Südwesteuropa, bis zum 15. herrschte dementsprechend heitere und trockene Witterung bei uns. Dann kam fast ganz Europa in den Bereich einer tiefen nördlichen Depression, die Bewölkung nahm rasch zu, bei stürmischen Westwinden fielen am 18. und 19. starke Niederschläge. Das Wetter der letzten Woche des Monats wurde ganz von einem rasch entstandenen und sich verstärkenden Hochdruckgebiet über dem Kontinent beherrscht. Die Schweiz hatte allgemein wolkigen bis heiteren Himmel. Am 28. schliesslich verursachte die Annäherung des Randtiefs eines im hohen Norden gelegenen Minimums nochmals Trübung und den Beginn von Regenfällen.

Wie der Februar, war auch der März im Durchschnitt zu warm, wenn auch nicht so extrem wie jener. Die positive Abweichung der Temperaturmittel schwankt zwischen $\frac{3}{4}^{\circ}$ und $1\frac{1}{2}^{\circ}$. Die monatlichen Bewölkungsmengen finden wir fast durchweg übernormal, im Osten des Landes in stärkerer Masse, als im Westen. Die Sonnenscheinregistrierungen weisen in Genf und Lausanne einen Ueberschuss von 20 Stunden auf, an den andern Orten dagegen ein Defizit von etwas grösserem Betrage. Die Niederschläge haben im Neuenburger Jura, sowie an den Bergstationen der Mittel- und Ostschweiz höhere Beträge erreicht, als dem langjährigen Durchschnitt entspricht, im übrigen waren die Abweichungen von den Mittelwerten nicht beträchtlich und teils positiv, teils negativ.

Am Anfang des Monats lag hoher Druck über dem Kontinent mit zwei durch eine flache Einsenkung getrennten Zentren in Frankreich und Westrussland. Nordeuropa war dagegen von einem tiefen Depressionsgebiet bedeckt, dessen Einwirkung am 1. und 2. bis zu uns reichte und uns trübes Wetter und einigen Niederschlag brachte. Die beiden folgenden Tage waren im ganzen heiter. Vom 5. bis zur Mitte des Monats sehen wir den hohen Druck auf Westeuropa beschränkt, während die Minima vom hohen Norden südöstliche Bahn nach Russland hinein verfolgen und die Witterung der Schweiz nun stärker beeinflussen. Am 5. traten beträchtliche Schneefälle ein (Grindelwald 36 cm Neuschnee), bei starkem Rückgang der Temperatur. Auch der 7. und 8. waren reich an Niederschlägen (Säntis 37 und 59 mm), während zwischen 10. und 12. die gefallenen Mengen geringer waren. Vom 13. an breitete sich der hohe Druck von Frankreich allmählich gegen Norden und Osten aus, wodurch unser Land aus dem Bereich des Tiefdruckes im

Nordosten Europas mehr herauskam. Es folgte daher eine Periode heiteren oder wolkigen, überwiegend trockenen Wetters, die bis zum 20. andauerte. Zu Anfang der letzten Monatsdekade machten sich kleinere Wirbel am Südrand der nun von Nord- bis Mitteleuropa reichenden Antizyklone bei uns geltend. Die Schweiz erhielt zeitweise Schneefall bei Bise und unter erheblicher Abkühlung. Vom 24. an wurde der Hochdruck langsam ostwärts gedrängt durch die in den Kontinent eindringenden atlantischen Depressionen und ihre Teilwirbel. Nach föhniger Aufheiterung am 25. und 26. fiel am 27. und 28. allgemein ziemlich ergiebiger Regen beiderseits der Alpen. Die letzten Monatstage waren vorwiegend stark bewölkt und es kam nochmals zu etwas Regen, vornehmlich am Südfuss der Alpen.

Der April ist als warm, trocken und ziemlich heiter zu bezeichnen. Die Abweichungen der Monatsmittel der Temperatur schwanken um $+1\frac{1}{2}^{\circ}$, die höchsten Werte ($+2^{\circ}$) zeigen die Bergstationen. Der Ausfall an Niederschlag ist in der östlichen Hälfte des Mittellandes am grössten, hier ist nur $\frac{1}{3}$ bis $\frac{1}{2}$ der normalen Mengen gemessen worden in der Westschweiz etwa $\frac{2}{3}$. Alpentäler und Gipfel haben geringere Defizite, stellenweise ist es hier auch zu Ueberschüssen gekommen. Die Bewölkungszahlen liegen in der Südwestschweiz etwas zu hoch, sonst allgemein unter dem Durchschnitt, die Sonnenscheinapparate haben im ganzen 25—30 Stunden mehr registriert, als normal ist.

Zu Anfang des Monats herrschte antizyklonale Witterung über dem Kontinent, unsere Stationen meldeten heiteren Himmel und, namentlich in der Höhe, relativ hohe Temperaturen. Am 5. verursachte eine kleine Randstörung, im Gebiet des Kanals, stärkere Bewölkung und etwas Regen bei uns; die beiden folgenden Tage waren wieder heiter. Ein von England gegen die Ostsee ziehendes Minimum beeinflusste die Witterung dann nachdrücklicher: vom Abend des 8. an erhielt unser Land mit einem Kälteeinbruch Niederschläge, die bis zirka 900 m herab als Schnee fielen und besonders in der Höhe beträchtlich waren (Säntis am 9. und 10. zusammen 64 mm, Gotthard am 10. 29 mm). Nach Vorübergang dieser Depression breitete sich rasch wieder hoher Druck von Westen her über Europa aus, und wir erhielten eine Schönwetterperiode, die vom 11. bis zum 16. dauerte. Während der folgenden Woche überlagerte ein umfangreiches vom atlantischen Ozean kommendes Tiefdruckgebiet, in dem sich zahlreiche Teilwirbel bildeten, den ganzen Kontinent und die Schweiz hatte dementsprechend in dieser Zeit, vor kürzeren, zum Teil föhnigen Aufheiterungen abgesehen, stark bewölkt, im ganzen kühles Wetter und fast täglich Niederschläge, die in der Nacht zum 20. bis 700 m herab Schneedecke brachten und besonders südlich der Alpen bedeutende waren (Lugano 68 mm). Zum Schluss dieser Depressions-tätigkeit sieht man auf den Wetterkarten vom 24. bis 26. die Mittelmeerdepression sich vertiefen und rasch nordwärts über die Alpen bis zum Kanal wandern. Die Folge waren sehr intensive Regenfälle in der Südschweiz, trübes Wetter mit geringem Regen nördlich der Alpen, mit Ausnahme des

25., wo bei starkem Föhn strichweise leichte Bewölkung herrschte. Am 28. wurde die Aufklärung allgemein, und auch an den beiden letzten Tagen des Monats war vorwiegend heiterer Himmel zu verzeichnen.

Der **Mai** war kalt, trübe und nass. Das Monatsmittel der Temperatur stand durchschnittlich $1\frac{1}{2}^{\circ}$ unter dem normalen, das der Bewölkung übertraf das normale überall beträchtlich, und die Niederschlagssummen erreichten und überstiegen stellenweise das Doppelte der durchschnittlichen Maimengen. Die Zahl der hellen Tage war sehr gering, die der trüben vielfach doppelt so gross als normal, und die Sonnenscheinautographen registrierten ein Zuwenig von 40—50 Stunden im Monat.

Während der ganzen ersten Dekade des Mai war Europa von einem ausgedehnten aber sehr flachen Depressionsgebiet überlagert, das stets mehrere Kerne der Wirbeltätigkeit aufwies. Sein Herannahen von Südwesten her verursachte am 1. Mai im Alpengebiet starken Föhn; entsprechend lagen die Temperaturen ungewöhnlich hoch (Zürich 30°). An den folgenden Tagen setzten Niederschläge ein, die anfangs nur im Tessin erheblich waren. Am 4. erhielten auch die übrigen Landesteile grössere Mengen, am meisten der Westen; bis 1300 m herab fiel Schnee. Auch weiterhin blieb das Wetter regnerisch und die Temperatur niedrig. Am 7. lag die Schneegrenze bei 700 m Meereshöhe und der Rigi meldete 38 cm Neuschnee. Nach Verstärkung des Luftdruckes über Zentraleuropa hatte die Schweiz dann zwischen 10. und 12. heiteres Wetter. Aber schon am 13. waren wir wieder im Bereich eines zur Nordsee gelangten Minimums, aus dem sich weiterhin eine von Nord- und Ostsee bis Nordafrika reichende Tiefdruckrinne entwickelte. Wir erhielten mit kräftiger Abkühlung starke Niederschläge, die im Tessin besonders reichlich ausfielen (Locarno am 16. 142 mm). Mit der allmählichen Ausfüllung dieses Tiefdruckes trat am 20. Aufhellung ein, die zunächst bis zum 22., dann, nach kurzer, leichter Unterbrechung, weiter vom 25. bis 27. anhielt. Die Witterung der letzten Monatstage beherrschte eine neue tiefe, bei England erschienene Depression; bei meist bedecktem Himmel war es wieder kühl und regnerisch bei uns. Am 30. und 31. fielen beträchtliche Mengen Regen oder Schnee, am letzteren Tage in Begleitung von Gewittern.

Der **Juni** 1926 gehört zu den kältesten Junimonaten unserer 60-jährigen Beobachtungsreihe, wenn auch die extremen Verhältnisse des Jahres 1923 nicht erreicht wurden. In den zentralen und östlichen Teilen des Landes betrugen die negativen Abweichungen der Monatsmittel fast 3° , in den westlichen Teilen und auf den Gipfeln $2\text{—}2\frac{1}{2}^{\circ}$, südlich der Alpen ca. 1° . Zudem haben auch die monatlichen Niederschlagsmengen überall, mit Ausnahme des Südwestens, die normalen Beträge überschritten, und ebenso ist die Zahl der Niederschlagstage und der Grad der Bewölkung relativ hoch ausgefallen, während die Sonnenscheinregistrierungen ein Defizit von durchschnittlich 30 Stunden angeben. Der Monat hatte also ausgesprochen kalten, nassen und trüben Charakter.

Beim Betrachten der täglichen Wetterkarten findet man während der ersten beiden Drittel des Monats stets denselben Typus der Druckverteilung: hohen Druck über Südwesteuropa und im hohen Norden, dazwischen eine breite, flache und unregelmässig gestaltete Rinne, in der zahlreiche grössere und sekundäre Wirbel über den Kontinent hinziehend aufeinander folgten. Die Witterung unseres Landes war von diesen Minima wegen der Nähe ihrer Bahn stets stark beeinflusst, es kam fast täglich zu Niederschlägen, die zunächst am 2. im Tessin, am 3. und 4. in der Ostschweiz sehr bedeutend waren. Am 12. abends ging mit einer Böenlinie ein gewaltiger Gewittersturm über das Land, der im Neuenburger Jura zirka zwanzig Häuser zerstörte. In der Nacht zum 14. erhielt dann das Tessin ein heftiges Gewitter mit ungewöhnlich starkem Regen. Vom 20. an breitete sich die südwestliche Antizyklone mehr nord- und etwas ostwärts aus, wodurch die Schweiz zunächst Aufheiterung erhielt. Am 22. abends verursachte die Passage der Böenlinie einer im Gebiete der Nord- und der Ostsee liegenden Depression wieder heftige Gewitter, namentlich in der Zentralschweiz (Pilatus 94 mm Niederschlag mit starkem Hagel). Nach einigen wolkgigen und namentlich im Osten noch regnerischen Tagen ist dann der Schluss des Monats vom 26. an, einer kräftigeren Ausbreitung des Hochdrucks gegen Osten entsprechend, überwiegend heiter gewesen.

Dem ungewöhnlich kalten Juni folgte ein im Ganzen ebenfalls zu kühler **Juli**, mit einer Abweichung des monatlichen Temperaturmittels von durchschnittlich -1° auf der Nordseite der Alpen. Auch der Grad der Bewölkung war wieder, vom äussersten Südwesten des Landes abgesehen, allgemein übernormal, und speziell ist der Ausfall an „hellen“ Tagen (mittlere Bedeckung des Himmels unter $\frac{2}{10}$) beträchtlich gewesen. Bei den Niederschlagsmengen finden sich an den Bergstationen und in einzelnen Gebieten namentlich der Ost- und Zentralschweiz grössere Ueberschüsse, sonst geringer positive und teilweise auch negative Abweichungen. Die Sonnenscheinregistrierungen weisen Defizite auf, die in der Ostschweiz am grössten sind (70 Stunden), nach Westen hin geringer werden und im Südwesten des Landes fast ganz verschwinden. Für die Südseite der Schweizeralpen war der Juli ein heiterer, trockener und normal warmer Monat.

Zu Anfang des Monats lag hoher Luftdruck über Nordeuropa, relativ niedriger über den Mittelmeerländern. Die Schweiz hatte leichte Bise und heiteren oder durch Hochnebel bewölkten Himmel. Mit der Verflachung des Druckes über dem Kontinent entstanden dann auch nördlich der Alpen bis gegen England hin leichte Wirbel, die vom 4. an beiderseits der Alpen gewitterige Regenfälle hervorriefen, von denen die Südwest- und die Südschweiz, sowie die Berglagen am stärksten betroffen wurden (am 6. Lausanne 32 mm, am 7./8. Interlaken 45 mm, Montreux 38 mm, Lugano 76 mm Regen, Säntis 35 cm Neuschneehöhe). Das bewölkte und regnerische Wetter hielt bis zum Anfang der zweiten Dekade an. Nach leichter Verstärkung des Luftdruckes über dem Festland waren dann die Tage vom 13. bis 18. heiter und warm.

Nur am 14. kam es abends zu lokalen Gewittern. In der Nacht zum 20. vollzog sich der Vorübergang der Hauptböenlinie eines von England nach der Ostsee ziehenden Minimums wiederum unter Gewittererscheinungen beiderseits der Alpen, wobei besonders die Zentralschweiz starken Regen erhielt (Rigi 70 mm). Da dem ersten Wirbel weitere folgten, blieb der Witterungscharakter auch die folgenden beiden Tage veränderlich, dagegen standen dann der 23. und 24. unter antizyklonalem Einfluss und waren heiter und warm. Nach dem 25. und 26., die beide durch eine nördliche Depression wieder starke Bewölkung erhalten hatten, nahm der Luftdruck über Westeuropa, nordwärts bis über die britischen Inseln hinaus, rasch und kräftig zu, während er im Innern des Kontinents niedrig blieb, was die lebhaftere Zufuhr kalter polarer Luft für uns zur Folge hatte. Der Schluss des Monats war daher auf der Nordseite der Schweizeralpen trübe, regnerisch und ungewöhnlich kalt (Tagesmittel der Temperatur in Zürich am 28. $7\frac{1}{2}^{\circ}$ unter normal). Die grössten Niederschlagsmengen, bis ca. 1500 m herab als Schnee, wurden am Morgen des 28. gemessen (Rigi 53 mm, Einsiedeln 47 mm).

Der **August** erscheint, im Gegensatz zu den beiden vorangegangenen Sommermonaten, für Nord- wie Südschweiz als heiterer, sehr trockener und im ganzen warmer Monat. Im Jura und in der östlichen Hälfte des Mittellandes zeigen sich leichte negative Anomalien des Temperaturmittels, sonst finden wir überall positive Abweichungen, die nach Westen hin und mit der Meereshöhe grösser werden. Die Niederschlagsmengen machen durchschnittlich nur $\frac{1}{3}$ bis $\frac{1}{2}$, auf dem Säntis sogar nur $\frac{1}{3}$ der normalen Beträge aus; auch die Zahl der Niederschlagstage war allgemein bedeutend kleiner als gewöhnlich. Für die meisten Stationen ist der mittlere Bewölkungsgrad ebenfalls beträchtlich unternormal gewesen; die Gipfel treten hier wieder besonders hervor, der Säntis hatte zirka dreimal mehr „belle“ Tage, als nach dem langjährigen Durchschnitt im August zu erwarten sind. Demgemäss weisen auch die Sonnenscheinregistrierungen durchweg Ueberschüsse auf.

Bei hohem Luftdruck über West- und Nordwesteuropa begann der August bei uns mit heiterem Wetter. Die Ausbildung einer kleinen Depression südlich der Alpen gab dann Anlass zur Trübung des Himmels, wobei in der Nacht zum 4. starke, gewitterige Regenfälle im Tessin und in der Südwestschweiz und am folgenden Tag leichtere Niederschläge auch in der übrigen Schweiz eintraten. In der Nacht zum 8. brachten die Böenlinien einer kleinen nördlichen Randdepression der Nordseite der Alpen von neuem starken Niederschlag unter Gewittererscheinungen (Neuschnee bis 2000 m herab). Ein Vorstoss hohen Druckes von Westen in den Kontinent hinein hatte für den 9. und 10. Aufheiterung zur Folge. Die beiden nächsten Tage waren dagegen, unter dem Einfluss eines rasch nachfolgenden Minimums, bereits wieder trübe und niederschlagsreich. Nach neuer Verstärkung des Luftdruckes über dem Festland blieben wir dann vom 13. an bis zum Ende des Monats in ausge-

sprochenem Antizyklonalregime, mit heiterem oder wolkigem, vorwiegend trockenem und teilweise sehr warmem Wetter. Regen fiel während dieser Periode nur am 17. (Gewitter), zudem in Ost- und Mittelschweiz in geringen Mengen am 18., in erheblicherem Betrage am 22., an beiden Tagen veranlasst durch die Ausläufer von Böenlinien im Norden vorüberziehender Minima.

Der **September** war im ganzen ausserordentlich warm dazu heiter und trocken. Die positiven Abweichungen der Monatsmittel der Temperatur überstiegen fast überall 2° , in der Westschweiz sogar $2\frac{1}{3}^{\circ}$, Werte, die in den letzten 30 Jahren kaum mehr erreicht worden sind. Die Defizite des Niederschlages waren in der Ostschweiz am grössten und nahmen von da westwärts ab; St. Gallen und Säntis verzeichneten rund $\frac{1}{3}$, Luzern $\frac{2}{3}$, Neuchâtel $\frac{3}{4}$ der normalen Regenmengen. Die mittlere Bewölkung lag überall unter dem langjährigen Durchschnitt, in ungewöhnlichem Masse besonders im Gebiet des Genfersees und südlich der Alpen. Die Sonnenscheinregistrierungen weisen am Genfersee fast 100 Stunden, in den meisten andern Gegenden 50—60 (auf dem Säntis dagegen nur 13) Stunden Ueberschuss auf.

An Stelle des Hochdruckes, der während der zweiten Hälfte August den Kontinent bedeckt hatte, trat zu Anfang September gleichmässig flacher Druck; die Schweiz erhielt für die ersten Tage des Monats warmes und schwüles, meist stärker bewölktes Wetter mit Gewittern. Vom 6. an zeigten die Wetterkarten dann wieder deutlicher ausgeprägte Verhältnisse: tiefen Druck über Nordeuropa, dagegen neue Druckzunahme über dem Kontinent. Damit begann für unser Land eine Periode heiteren, trockenen Wetters, in der die Temperaturen sehr hoch anstiegen. Sie erfuhr eine kurze Unterbrechung am 12., wo nach sehr warmem, föhnigem Tag abends der Vorübergang einer Böenlinie Gewitter und Abkühlung brachte sowie Niederschläge, die strichweise auch am 13. noch anhielten. Schon am 14. war die Hochdrucklage wieder hergestellt, die nun ohne weitere Störung, mit schönem Herbstwetter, bis zum 23. bestehen blieb. Mit ihrem Zerfall wurde dann der Einfluss des nördlichen Tiefdruckgebietes bis zu uns hin fühlbar. Am 24. überzog sich der Himmel, am 25. begann Regen, der tags darauf recht erhebliche Mengen, stellenweise über 30 mm, lieferte und auch am Morgen des 27. noch andauerte. Zugleich ging die Temperatur stark zurück. Während der letzten Tage des Monats war schliesslich, nach neuer Zunahme des Druckes, der Himmel bei uns wieder allgemein leichter bewölkt.

Der **Oktober** ist, wie der September, durchschnittlich warm ausgefallen; im Gegensatz zu jenem war er aber niederschlagsreich und ziemlich trübe. Die Mitteltemperatur lag rund 1° über der normalen, im Westen und namentlich im Südwesten wurde dieser Wert etwas überschritten, in den höheren Lagen dagegen vielfach nicht erreicht. Die monatlichen Niederschlagssummen zeigen in der östlichen Hälfte des Mittellandes nur leichte Abweichungen, sonst überall ein zuviel bis etwa 70% des langjährigen Durchschnittes. Die Bewölkungszahlen lagen, ausgenommen im

Südwesten und im Süden des Landes, durchweg über den mittleren; die registrierte Sonnenscheindauer ist im grossen und ganzen nicht weit von der normalen abgewichen.

Zu Monatsbeginn verstärkte sich der Luftdruck über dem Kontinent zu einer ausgedehnten Antizyklone, und die Schweiz erhielt trockenes, auf den Höhen heiteres, in den Niederungen zeitweise nebliges Wetter, das bis zum 6. anhielt. Vom 7. an kamen uns, nach raschem Zerfall des Hochdrucks, die atlantischen Wirbel wieder näher. Infolge Föhnwirkung fielen die Regenmengen zunächst nicht erheblich aus, immerhin hat der Genfersee in der Nacht zum 8. einen Gewitterregen von 20 mm Ertrag erhalten. Grössere Mengen brachte dann die Passage einer Böenlinie am 10. Der 11. war vorübergehend heiter, nachdem sich ein Hochdruckkeil von Südwesten her vorgeschoben hatte. Vom 12. bis 14. herrschte wechselnd bewölkttes Wetter mit leichten Regenschauern; während der folgenden Tage blieben die Depressionswirkungen nördlich von uns, wir hatten antizyklonal heiteren Himmel bis zum 17. Am 18. setzten, mit dem Einbruch kalter Luftmassen von Nordeuropa her, starke Abkühlung, Bewölkungszunahme und Regen ein; doch heiterte es nach starkem Druckanstieg rasch wieder auf. Vom 20. an bildete sich dann im Innern des Kontinents ein grosses Depressionsgebiet aus mit verschiedenen Wirbelzentren, so dass eine Periode trüben und regenreichen Wetters für uns begann (Lausanne am 21. 59 mm, Chur am 23. 40 mm Regen, Säntis 21.—27. zusammen 120 cm Neuschnee). Der 27. war im Regime eines Hochdruckkeils vorübergehend heiter; die folgenden Tage bis zum Ende des Monats lagen wieder unter dem Einfluss eines von der Biskaya her langsam nordostwärts sich entwickelnden furchenartigen Minimums. Bei leichter Föhnlage kam es von neuem zu beträchtlichen Niederschlägen, das Tessin erhielt in der Nacht zum 31. ein Gewitter, das Locarno 58 mm Regen lieferte. Am letzten Tag des Oktober erreichten die Temperaturen bei bewölkttem, föhnigem Wetter relativ hohe Werte.

Die Witterung des **November** war besonders durch extreme Wärme ausgezeichnet. Die positiven Abweichungen des Monatsmittels der Temperatur lagen im Mittelland nahe bei 2°, an den Gipfelstationen bei 3°, in den Alpentälern zwischen 3 und 4° und darüber. Der Monat gehört damit für uns zu den wärmsten Novembermonaten der letzten 60 Jahre, stellenweise, vor allem in den Föhntälern, wurden höhere Mittel bisher nicht aufgezeichnet. Auch in den Beobachtungen von Lugano findet man gleich hohe Novembertemperaturen seit 1898 nicht wieder. Die Niederschlagsmengen weichen von den normalen teils in positivem, teils in negativem Sinne ab, im allgemeinen um mässige Beträge; nur Lugano fällt durch sehr grossen Ueberschuss auf. Bei der Bewölkung lässt die fast durchweg unter normale Zahl „heller“ sowohl, wie „trüber“ Tage ein Vorherrschen mittlerer Bewölkungsgrade erkennen. Die Sonnenscheindauer weist in Lugano ein Defizit von 44, auf dem Säntis von 26 Stunden, sonst ziemlich allgemein ein Mehr von 10—20 Stunden auf.

Der Witterungscharakter des November wurde durch eine mit geringen Schwankungen fast den ganzen Monat hindurch anhaltende Lage bestimmt, bei der hoher Druck den Osten und Südosten, tiefer Druck die westliche Hälfte Europas bedeckte. Deshalb war die Zufuhr kalter Luft relativ selten, dagegen Föhnbildung häufig (Altdorf 12 Föhntage). Zu Anfang des Monats lagen die Niederungen vorwiegend unter einer Hochnebeldecke, die Höhen waren meist heiter. Das Tessin hatte während der ersten Dekade täglich Regen. Am 7. erhielt mit der Annäherung einer Böenlinie auch die Alpennordseite Niederschläge; die Passage der Linie ging dann abends, nach kurzer, föhniger Aufheiterung, mit Regenböen und Gewittern vor sich. Zwischen 10. und 14. herrschte, von Nebeln abgesehen, heiteres Wetter, zuletzt mit deutlicher Föhnwirkung. Auch die folgenden Tage waren relativ leicht bewölkt, am 17. und 18. wiederum unter Föhneinfluss (starker Regen im Tessin). Am 19. nachmittags setzte Niederschlag auch nördlich der Alpen ein und zugleich etwas Abkühlung. Stark bewölkt und regnerisch blieb es dann noch weiterhin. Grosse Niederschlagsmengen fielen auf der Nordseite am 21., im Tessin täglich vom 18. bis 24. Zwischen 25. und 28. hatten wir, bei gleichmässigerer Druckverteilung über dem Festland, trockenes und meist heiteres Wetter. Am 29. zeigte sich auf den Wetterkarten von neuem ein Tief über Frankreich, während hoher Druck über Südrußland lagerte. Die Folge war heftiger Föhn am Morgen des 30. in den Tälern und Süd Sturm auf den Gipfeln, sowie neue starke Regenfälle südlich der Alpen.

Der **Dezember** war auf der Nordseite der Alpen kälter, dazu im ganzen trüber, aber niederschlagsärmer als normal. Der Wärmeausfall übersteigt im Südwesten und in den höheren Lagen 1°, sonst erreicht er etwa $\frac{1}{2}$ °. Die Niederschlagsmengen sind in den Berglagen der Zentral- und der Ostschweiz etwas zu gross ausgefallen (Säntis sogar um fast das $2\frac{1}{2}$ -fache), die übrigen Landesteile dagegen erhielten nur $\frac{1}{3}$ bis $\frac{1}{2}$ der Durchschnittsbeträge. Der Bewölkungsgrad blieb im Rhonetal und in der oberen Hälfte des Genferseegebietes unter dem langjährigen Mittel, sonst wurde dieses auf der Nordseite der Alpen allgemein überstiegen. Ein exzessiv heiterer und warmer Monat war der Dezember für das Tessin, wo die Beobachtungen nur die Hälfte der normalen Bewölkung und einen Wärmeüberschuss von $1\frac{3}{4}$ ° ergeben haben.

Am Anfang des Monats sehen wir auf den Wetterkarten die Entwicklung eines kontinentalen Hochdruckes noch durch kleinere Depressionen von der Ostsee wie vom Mittelmeer her gestört; es bildete sich schliesslich eine flache Tiefdruckrinne zwischen Norwegen und Balkan. Die Witterung war daher vorwiegend trübe und es kam anfangs zu vereinzeltten, zwischen 4. und 6. zu verbreiteteren Schneefällen. Vom 7. bis 14. beherrschte dann eine Antizyklone mit Kern über Westeuropa die Witterung unserer Gegend; die Höhen hatten vorwiegend heiteren Himmel und zeitweise relativ hohe Temperaturen, die Niederungen lagen meist unter einer Nebeldecke. Vom 14. an zog sich der hohe Druck gegen Westen zurück; die Minima schlugen von Skandinavien süd-

östliche Bahn gegen Polen ein, so dass wir unter ihren Einfluss kamen. Bis zum 22. herrschte nun stark bewölktes Wetter vor mit Regen- und Schneefällen, von denen im allgemeinen der Osten des Landes — insbesondere die Berglagen — stärker betroffen wurde als der Westen. Nach Zunahme des Luftdruckes im Bereich der Nordsee entstand darauf in der Schweiz Bisenlage, die mit kaltem, in den Niederungen trübem, auf den Höhen meist heiterem Wetter bis zum 28. anhielt. Am 29. kam es, nach dem raschen Durchbruch eines Minimums von Island zur Ostsee, mit Erwärmung zu neuem Regen- und Schneefall, der wiederum die erheblichsten Mengen dem Osten und den Bergen lieferte (Säntis 60 mm). Der 30. Dezember war dann noch stark bewölkt, der 31. wieder hell.

Zusammenfassung: Das Jahr 1926 brachte erhebliche Abweichungen von den normalen Verhältnissen und beträcht-

liche Gegensätze im Witterungscharakter. Die ersten vier Monate waren warm, der Februar speziell in extremer Masse. Dabei war der Januar — für den Süden und den Südwesten auch der Februar — ziemlich reich an Niederschlägen, der April dagegen allgemein trocken. Kalt und trübe waren die Monate Mai, Juni und in geringerem Masse auch der Juli. Insbesondere hat sich der Juni durch ungewöhnlich niedrige Mitteltemperaturen auszeichnet. In der zweiten Jahreshälfte treten der August durch geringe Bewölkung und grosse Trockenheit, die nachfolgenden Herbstmonate, namentlich September und November durch ausserordentlich hohe Mitteltemperaturen hervor. Der September war zudem von heiterem und trockenem Witterungscharakter. Dem warmen November folgte ein ziemlich kalter, trüber, aber im ganzen niederschlagsarmer Dezember.

Monatswerte der wichtigsten meteorologischen Elemente 1926.

*) Basel hat einen empfindlicheren Heliographen, als die übrigen Stationen.

**) Für Genf sind hier die Angaben seines älteren Heliographen benutzt (vergl. Anhang Nr. 4, Seite 1).

Nr. 2.

Ergebnisse der Niederschlagsmessungen auf den meteorol. Stationen I.—III. Ordnung im Jahre 1926.

Die Aenderungen im Netze der Meteorologischen und Regenmess-Stationen finden sich in der Einleitung pag. III dieses Bandes angegeben.

Monats- und Jahressummen

der Niederschlagsmessungen sämtlicher meteorol. Stationen I.—III. Ordnung im Jahre 1926.

Bei Zählung der Niederschlagstage sind in dieser Tabelle nur die Tage mit mindestens 1,0 mm berücksichtigt worden.

Die mit * bezeichneten Summen sind nach den Nachbarstationen interpoliert.

Die Niederschlagsbilanz des Jahres 1926.

Ergebnisse der im Alpengebiete aufgestellten Totalisatoren.

Der Firnzuwachs in einigen Gebieten der Schweizeralpen.

Einzelne bemerkenswerte Niederschläge im Jahre 1926.

Die Niederschlagsbilanz des Jahres 1926.

Das Berichtjahr hat auf der Alpensüdseite recht beträchtliche Mehrbeträge über die Normalwerte der Niederschlagsmengen gebracht. So erhielt Lugano 130% der letzteren, und der Ueberschuss ist vielerorts noch grösser (Brissago 136, Biasca 149, Airolo 155%). Von den Pass-Stationen massen St. Bernhard 124, St. Gotthard 124 und der Bernhardin gar 155%, wie denn auch das südöstliche Alpengebiet noch recht ansehnliche Ueberschüsse hatte (Bevers 146, Davos 122, Chur 123%). Aber auch in den übrigen Alpentälern war das Plus noch ansehnlich (Göschenen 116, Reckingen 120, Beatenberg 111%). — Im Mittelland wurden ungefähr die normalen Mengen gemessen: St. Gallen 98, Zürich 93, Luzern 100, Bern 109, Lausanne 101% und nur Genf nimmt am Plus der Südschweiz teil (120%). Die Gipfelstationen dagegen zeigen beträchtliche Ueberschüsse: Rigi 136, Säntis 133%. Der Nordwestfuss des Jura verzeichnet in Basel mit 86% ein nicht unerhebliches Defizit.

Die Niederschlagshäufigkeit ist — beurteilt

nach der Anzahl der Tage mit Niederschlag — südwärts der Alpen trotz den grösseren Jahresmengen eher kleiner als normal; Lugano hatte zwei Niederschlagstage weniger als im langjährigen Durchschnitt. Nordwärts der Alpen ergibt sich abgesehen vom Schaffhausergebiet (Unter-Hallau -7) ein Plus: Zürich +10, Bern +20, Genf +27.

In der Tabelle auf pag. 9 sind auch für die einzelnen Monate die Prozentverhältnisse der diesjährigen zu den normalen Mengen für eine Reihe von Stationen mitgeteilt. Man ersieht daraus den Niederschlagsreichtum des Januar in der Westschweiz und auf den Höhenstationen; der Februar war auf der Alpensüdseite und in Genf ergibig an Niederschlägen. Bemerkenswert war die Trockenheit des April im Osten, während Mai und Juni im ganzen Lande sehr häufige und auch ergibige Niederschläge brachten, August und September nord- und südwärts der Alpen sehr trocken ausfielen. Ungewöhnlich gross waren die Niederschläge im November am Südhang der Alpen und in Bünden.

Ergebnisse der im Alpengebiete aufgestellten Totalisatoren.

Die nachstehende Tabelle gibt die Resultate der im Berichtjahr funktionierenden Totalisatoren. Statt einiger zerstörter oder aus andern Gründen aufgebener Apparate des Mattmarkgebietes finden sich dabei einige andere Apparate jenes Gebietes, die zwar nicht erst mit dem Berichtjahr in Betrieb genommen, deren Resultate aber bisher an dieser Stelle nicht veröffentlicht wurden. Es sind dies: Weisstal, am rechtseitigen (östlichen) Talhange über dem Hotel Mattmark auf vorspringendem Felsen in 2270 m (ca. 200 m über der Saaser-Visp);

Ofentalpass, in 2800 m auf Felsrippe zwischen Ofentalpass und Ofentalgletscher (280 m westlich der Passlücke); Seewinenberg, 3025 m, auf dem Grat, der den Seewinengletscher vom Haupttal trennt; Allalingletscher, auf einer Felsinsel mitten im Allalingletscher in 3360 m. — Erstmals wird auch mitgeteilt das Resultat des östlich des Simplons im oberen Binntal am Geisspfadsee in 2480 m plazierten Apparates. — Vom Skopi werden diesmal die Resultate zweier Apparate gegeben, auf die weiter unten eingegangen werden soll.

Für die langjährigen Beobachtungsstationen ist in der Klammer angegeben, wie viel die Niederschlagsbeträge des genannten Zeitraumes in $\frac{0}{0}$ der durchschnittlichen Jahresmengen ausmachen. Man ersieht daraus, dass vom 1. September 1925 bis 31. August 1926 allgemein nicht unbedeutend mehr Niederschlag fiel, als es dem langjährigen Durchschnitt entspricht. Im Wallis beträgt das Plus — Zermatt macht eine Ausnahme — rund $\frac{1}{3}$ und zwar von der Sohle des Haupttales (Sion 120, Reckingen 121 $\frac{0}{0}$) bis zum St. Bernhard (118 $\frac{0}{0}$). Auch im Berner Oberland (Guttannen 117, Beatenberg 121 $\frac{0}{0}$) und im Gotthardgebiet (St. Gotthard 115, Airolo 117 $\frac{0}{0}$) ist der Ueberschuss nicht viel kleiner. Weiter östlich kommt von den alpinen Stationen nur der Bernhardin (118 $\frac{0}{0}$) auf ein so grosses Plus, sonst ist es etwas kleiner (Auen/Linth 106, Savognin 112, Bevers 112, Klosters 103 $\frac{0}{0}$). Dagegen haben die eigentlichen Gipfelstationen der Voralpen einen noch grösseren Ueberschuss (Rigi 133, Säntis 154 $\frac{0}{0}$).

Das gibt einige Anhaltspunkte für die Beurteilung der Totalisatorresultate. Becca d'Audon kommt

diesmal mit 187 cm wesentlich über die Jahressumme von Diablerets-Village (149 cm), dokumentiert aber doch eine relative Niederschlagsarmut dieses Gebietes. Der Apparat auf Cold'Orny gibt mit rund 400 cm den zu erwartenden Ueberschuss von $\frac{1}{3}$ über die normale Jahresmenge. Gornergrat (151 cm) hat gegenüber Zermatt (60 $\frac{0}{0}$) einen bedeutenden Mehrbetrag und beweist die rein lokale Natur des diesjährigen Defizites von Zermatt. Die Apparate der Mattmarkgruppe figurieren mit Ausnahme von Galmenhorn, — das mit 107 cm unter dem Normale bleibt — zum erstenmal in dieser Zusammenstellung. Alle geben, soweit mir die früheren Jahresresultate bekannt sind, Jahresmengen, die über dem Mittel stehen; nur das in der Maximalzone gelegene Seewinenberg scheint weniger zu haben. — Sehr klein ist die Zunahme der Niederschläge im Binntal von Binn (115 cm) nach dem in einem oberen Seitentälchen gelegenen Geisspfadsee (124 cm). — Der Totalisator auf der Scheidfluh (Rhongletscher) zeigt mit 259 cm den nach seinen Basisstationen zu erwartenden Mehrbetrag, während Eggishorn (110 cm) und Konkordia-

platz (143 cm) nicht viel davon aufwiesen. Bei dieser Gelegenheit sei daran erinnert, dass die neue Beobachtungsreihe von Konkordiaplatz (seit 1921) eine um die Hälfte kleinere Jahresmenge liefert als die ursprüngliche Aufstellung, welche man als ungünstig bezeichnete. — Auch Jungfrauoch erreicht mit 269 cm bei weitem nicht die Mengen früherer niederschlagsreichen Jahre.

Im Gotthardgebiet ist namentlich die im exponiert aufgestellten Fibbiatotalisator aufgespeicherte Menge unter der nach dem St. Gotthard zu erwartenden, aber auch Lago Ritom bleibt darunter. Am Skopi überfloss der alte, am Westhange in 2700 m Höhe stehende Apparat, wie schon in früheren niederschlagsreichen Jahren, so dass die Jahressumme auf mindestens 425 cm angesetzt werden müsste. Ein solcher Niederschlagsreichtum dieses Gebirgsstockes ist schon öfters angezweifelt worden; man hatte daher im September 1925 am selben Hange in 2850 m Höhe einen zweiten Apparat installiert, von dem nun das erste Jahresresultat mit 285 cm vorliegt. Ohne persönliche Kenntnis der beiden Standorte möchte ich mich vorläufig nicht für eine der beiden Zahlen entscheiden. Auf jeden Fall zeigt die Differenz, wie vorsichtig man bei der Platzwahl der Totalisatoren, wie auch bei der Beurteilung ihrer Resultate sein muss.

Eine grössere als nach den Basisstationen zu erwartende Jahresmenge sammelte der Apparat am Claridenfirn mit mindestens 400 cm (er begann zu überlaufen); doch wird man sich dabei der noch mehr ausser Proportion zu den Fusstationen stehenden Jahressummen

von Rigi und Säntis erinnern müssen. Der glücklicherweise wieder in Stand gestellte Apparat bei der Silvrettahütte lieferte mit 168, ebenso wie derjenige auf dem Eckhorn mit 187 cm einen der grössten dort je gemessenen Beträge. Auch der nunmehr einzige Apparat im Nationalpark beim Blockhaus Cluozza hat noch nie so viel gesammelt wie dies Jahr (101 cm), trotzdem die Unter-Engadinstationen seit seinem Bestehen (1918/19) schon grössere Ueberschüsse nachwiesen. Dagegen hat Julier mit 103 cm nicht wesentlich mehr als im Durchschnitt, während auf Piz Scalotta mit 327 cm mehr gemessen wurde als zu erwarten war.

An dieser Stelle sind von Interesse die Vergleichszahlen von geschützten (Niphertrichter) und ungeschützten Ombrometern. Solche liegen vor vom Säntis, wo der Totalisator vom 3. Oktober 1925 bis zum 7. Juli 1926 412 cm Niederschlag sammelte, während im gewöhnlichen Ombrometer in derselben Zeit 301 cm als Summe der täglichen Niederschläge gemessen wurden. Das Verhältnis von geschütztem zu ungeschütztem Ombrometer ist somit 1.37; wenn man mit diesem Faktor den Säntisniederschlag im Totalisator für unsere ganze Vergleichsperiode vom 1. September 1925 bis 31. August 1926 berechnet, so ergibt sich 527 cm. Damit ist der Säntis bei weitem die niederschlagsreichste unserer bestehenden Stationen. — Auch auf dem St. Bernhard werden die Vergleichsmessungen von geschütztem und ungeschütztem Ombrometer fortgesetzt; in ersterem wurden in unserer Normalperiode 222, in letzterem 151 cm Niederschlag summiert, was einem Verhältnis von 1.46 entspricht.

Der Firnzuwachs in einigen Gletschergebieten der Schweiz pro 1925/26.

Der 13. Jahresbericht der Glätscherkommission der Physikalischen Gesellschaft Zürich¹⁾ führt aus:

„Das Berichtjahr zeigte bemerkenswerte Anomalien, bedingt durch folgenden Verlauf der Witterung in den höheren Alpenregionen.

Der Spätsommer 1925 hatte namentlich im ungewöhnlich kalten September zu verschiedenen Malen Neuschnee gebracht, der im Firngebiet nicht mehr zur Ablation kam. Sogar der Felsgipfel des Säntis trug mit Ausnahme weniger Tage eine Schneedecke; am 24. schneite er sodann vollständig ein. Die Höhen unter Säntisniveau wurden dagegen noch einmal schneefrei und blieben es im heiteren und trockenen Oktober. Vom 3. November an zeigten der St. Gotthard, vom 8. November an die Hochtallagen des Engadin, Davos etc. eine dauernde Schneebedeckung. Der Winter brachte nur mässige Schneehöhen; am 1. Januar lagen auf St. Gotthard 155, auf dem Säntis gar nur 135 cm, wobei

aber gesagt werden muss, dass die vielfach stürmischen Winde eine normale Schneeablagerung auf diesem Felsgipfel mehr als üblich verhindert haben dürften. Die Schneedecke erreichte auch in den folgenden Monaten keine grosse Mächtigkeit und betrug zu Anfang April auf St. Gotthard 180, auf Säntis 200 cm. Die maximale Schneehöhe des Winters auf dem St. Gotthard blieb der schlechten Maiwitterung vorbehalten und wurde am 21. mit 225 cm erreicht, gewiss eine Seltenheit für diese tiefe Lage. Für die Firnregionen verzögerte sich, wie wir sehen werden, der Zeitpunkt der maximalen Akkumulation noch recht beträchtlich, da der Juni relativ noch kälter als der Mai war; für die Passlagen und Voralpengipfel bedingte diese kalte Vorsommerwitterung wenigstens eine ungewöhnlich späte Ausaperung: der St. Gotthard wurde dies Jahr erst am 8. Juli, ungefähr gleichzeitig mit dem Säntis, schneefrei. Wer um diese Zeit in ihm bekannte Hochregionen kam, der war überrascht von dem gegen andere Jahre fast noch winterlichen Anblick der Landschaft.

Im Juli, der nur vereinzelte schöne Tage, in der letzten Pentade dagegen Neuschnee bis gegen 1300 m

¹⁾ Erstattet von R. Billwiller in der Vierteljahrsschrift der Naturf. Ges. Zürich, 71 (1922).

herab brachte, war die Ablation noch unbedeutend; erst die schöne und warme Witterung des August und September verursachte eine zwar späte, aber intensive Abschmelzung.

Die Kenntnis der vorstehend kurz skizzierten Witterungsverhältnisse erlaubt uns eine Interpretation der leider spärlich vorliegenden Meldungen aus unseren beiden Messgebieten; die schlechte Witterung um Weihnacht-Neujahr und im Mai-Juni begünstigte natürlich die Begehung des Gebirges durch Touristen wenig. Die trifft namentlich zu für

Clariden.

Datum.	Schneehöhe bei der Hütte	Firnzuwachs seit 1. Sept. 1925	
		untere Boje (2708 m)	obere Boje (2910 m)
1925 XI. 21.	?	115 $\frac{cm}{m}$	120 $\frac{cm}{m}$
1926 IV. 2.	305 $\frac{cm}{m}$	? "	480 "
V. 1.	320 "	? "	> 580 "
IX. 11.	— "	? "	415 "

Die untere Boje konnte nur einmal, im November, abgelesen werden; nachher war von ihr nichts mehr zu sehen, auch nicht im September, als sie längst hätte ausgeapert sein sollen. Bei der Jahresaufnahme, die in Verhinderung aller Kommissionsmitglieder von Herrn R. Bohner von der meteorologischen Zentralanstalt in Begleitung von Hüttenwart J. Dürst durchgeführt wurde, war sie trotz der an dieser Stelle kleinen Firnbewegung durch Sondierungen in der zu erwartenden Position nicht aufzufinden, was unsere Vermutung auf böswillige Zerstörung bestärkt. Im Messpunkte wurde eine neue, durch starken Pfahl unter Firnniveau verankerte, 5,6 m über den Firn herausragende Boje aufgepflanzt.

Ausserordentlich wertvoll ist die Ablesung an der oberen Boje vom 2. April, welche den damaligen Firnzuwachs zu 480 cm ermittelte (während bei der Hütte 305 cm lagen). Sie steht in sehr gutem Verhältnis zu den oben skizzierten Messungen unserer regulären meteorologischen Stationen und beweist, dass bis zu Anfang April die Akkumulation auch hier nicht allzumächtig war, da um diese Zeit nach einem schneereichen Winter von der Boje am oberen Claridenmessplatz nichts zu sehen ist. Die nachfolgenden reichlichen Schneefälle haben sie dann zugedeckt und noch gegen Ende August war nichts von ihr zu sehen; dann ermöglichte ihre Ausaperung die Feststellung des bis zum Tage der Jahresaufnahme (11. September) restierenden Firnzuwachses von 415 cm. Ihre Einmessung ergab die mit früheren Bestimmungen gut harmonisierende Jahresbewegung des Firns an dieser Stelle von 14,6 m gegen ENE. Die Bohrungen nach dem letztjährigen Ocker verliefen resultatlos. Im Fixpunkte wurde eine neue 5,8 m über Firnniveau emporragende Boje gestellt.

Der Totalisator auf dem Geissbützistock war schon im Juli als gefüllt gemeldet und ihm ein bestimmtes Quantum Wasser entnommen worden. Die Tatsache, dass bei der Entleerung am 10. September kein Oel mehr auf der Flüssigkeit schwamm, zwingt zu der

Annahme, es sei ein gewisses, wenn auch kleines Quantum durch Ueberlaufen für die Messung verloren gegangen und die Niederschlagsmenge vom 1. September 1925 bis 10. September 1926 etwas grösser ist als die gemessene von 400 cm. Die Summierung der täglichen Messungen des entsprechenden Zeitraumes von Linthal-Auen beträgt 147 cm.

Etwas häufigere Messungen liegen vor von unserem zweiten Messgebiete:

Silvretta.

Datum.	Firnzuwachs seit 17. September 1925	
	untere Boje (2760 m)	obere Boje (Silvrettapass 3013 m)
1926 II. 11.	240 $\frac{cm}{m}$	?
17.	240 "	230 $\frac{cm}{m}$
20.	300 "	250 "
III. 3.	? "	250 "
IV. 4.	? "	250 "
V. 2.	? "	300 "
24.	? "	375 "
VI. 6.	? "	400 "
IX. 6.	? "	225 "
11.	? "	190 "

Auch hier beschränken sich die Ablesungen im wesentlichen auf die obere Boje. Die untere zeigte am 20. Februar einen Firnzuwachs von 300 cm, und wir vernahmen dann erst wieder etwas von ihr bei der Jahresaufnahme, die am 11. September von Herrn cand. W. Leemann mit Führer A. Michaud besorgt wurde. Da wurde sie in sehr schiefer Lage aufgefunden; bei Annahme der gleichen Neigung unter Firnniveau käme man auf einen Jahreszuwachs von maximal 120 cm. Es wurde eine neue, senkrechtstehende, 415 cm über Firnoberfläche emporragende Boje gestellt. — Die Boje auf dem Silvrettapass zeigte am 20. Februar mit 250 cm einen um $\frac{1}{2}$ m weniger mächtigen Zuwachs an als die untere, offenbar wegen starken Schneeverwehungen auf dem Passplateau. Wertvoll sind die Ablesungen im Frühjahr und am 6. Juni, welche die bei der schlechten Witterung fortschreitende Akkumulation wenigstens bis zum letztgenannten Datum verfolgen lassen. Es kann als ganz sicher angenommen werden, dass die Boje nachher noch einschneite (die Ablesungen am nahen Weissfluhpegel ergaben die maximale Schneehöhe sogar im tieferen Niveau von 2740 m am 2. Juli!) und die Ablation in der Hauptsache erst im August einsetzte. Der resultierende Firnzuwachs betrug am 11. September an der Boje gemessen 190 cm, welcher Wert durch Ausgaben des im Herbst 1925 gestreuten Ockers in 199 cm Tiefe bestätigt wurde. Eine neue, 5 m über Firn emporragende Boje wurde unter Benutzung der alten als Verankerung aufgestellt.

Entsprechend der reichlichen Akkumulation und der sehr späten Ablation war der Silvrettagletscher wenig zerklüftet und konnte gut begangen werden; die Randkluft unter dem Totalisatorfelsen am Eckhorn war nur an einzelnen Stellen sichtbar und nirgends offen.

Die vom Totalisator am Eckhorn (in 3150 m) vom 16. September 1925 bis 11. September 1926 gesammelte Niederschlagsmenge ist mit 187 cm bei weitem die grösste dieser noch kurzen Beobachtungsreihe. Der Totalisator bei der Hütte (in ca. 2375 m), der bei der letztjährigen Jahresaufnahme undicht vorgefunden wurde, hatte letzten Herbst noch repariert werden können und vom 4. Oktober 1925 bis 11. September 1926 160 cm aufgenommen. Das macht reduziert — nach den Messungen von Klosters — für den Zeitraum des Eckhorntotalisators ca. 170 cm, und es würde sich somit im Berichtsjahr eine Zunahme der Niederschlagsmenge von der Hütte zum Silvrettapass ergeben. — Die Summe der täglich gemessenen Niederschläge in Klosters beträgt im gleichen Zeitraum 115 cm.

Die von Herrn J. Hess am Piz d'Err organisierten Schneehöhenmessungen ergaben für die östliche Firnmulde in ca. 3200 m bis zum 1. April 305 cm Firnzuwachs. Bei der Jahresaufnahme, die in Verhinderung des Herrn Hess durch Herrn Ing. J. Lugeon am 18. August vorgenommen wurde, betrug er immer noch 300 cm; die noch andauernde schöne Spätsommerwitterung wird ihn wohl noch erheblich reduziert haben. — Wie im letzten Bericht erwähnt, wurden am 31. August 1925 erstmals im aperi Firneis des untern Gletschers zu Ablationsbestimmungen Stangen versenkt; es konnte am 18. August 1926 bei der untern Stange in ca. 2798 m ein Abtrag von 56 cm konstatiert werden, bei der obern in ca. 2848 m ein solcher von 27 cm, obwohl an dieser Stelle noch 58 cm Schnee auf dem Eise lag. Das zwingt zu der Annahme, dass bis zu diesem Tage (18. August) der gemessene Abtrag bei der obern Stange noch ganz, derjenige bei der untern Stange zum grösseren Teil im Herbst 1925 erfolgte. — Da die Jahresaufnahme vom 18. August 1926 nur den Anfang der diesjährigen Ablationsperiode erfasst hätte, war eine spätere Ablesung von allergrösstem Interesse. Eine solche — veranlasst durch den Schreibenden und ausgeführt von Hrn. Krättli in Spinas — ergab für die anhaltende Schönwetterperiode bis zum 10. Oktober bei der untern Stange (2798 m) einen weiteren Abtrag von 129 cm Eis; bei der oberen Stange war am 10. Oktober nicht nur die Schneeschicht von 58 cm, sondern noch 106 cm Eis abgetragen (somit seit dem 31. August 1925 total 127 cm Eis).

Von den zahlreichen Schneehöhenmessungen an den unter dem Patronat des Skiklub Davos stehenden Pegeln des Parsenngebietes sei folgende, eine gute Uebersicht bietende Auswahl gegeben:

Parsenn.		Schneehöhe am Pegel	
Datum		bei der Hütte (2280 m)	an der Weissfluh (2740 m)
1925	XI. 11.	35 m	?

Charakteristisch für die diesjährigen abnormen Schneeverhältnisse des Frühsommers sind die Schneehöhen des 2. Juli mit noch 100 cm bei der Hütte, 285 cm an der Weissfluh!

Eine sehr schöne Reihe von Schneehöhenmessungen liegen wieder einmal vor vom Jungfraufirn, besorgt durch das Personal der Jungfraubahnengesellschaft. Ihr Beginn fällt mit dem 6. August 1925 gerade zusammen mit den Neuschneefällen, die das Ende der kurzen Ablationsperiode 1925 brachten.

Jungfraufirn.

Diese Messungen bestätigen aufs schönste alle festgestellten Eigentümlichkeiten über die Akkumulation und Ablation pro 1925/26: Relativ früher Beginn der Akkumulation im Spätsommer 1925, geringer Betrag derselben im Winterhalbjahr, ungewöhnlich mächtige und lang andauernde Akkumulation bis in den Juli hinein; die Ablation setzt in der Hauptsache erst im zweiten Augustdrittel ein und hält den ganzen September über an."

Herr Prof. Mercanton ermittelt für einige westschweizerischen Gebiete regelmässig den Firnzuwachs. Derselbe betrug am 3. Oktober auf Orny (in 3150 m) 2.0 m, am 13. Oktober auf Diablerets (2850 m) ebenfalls 2.0 m. Der relativ späte Termin der Jahresaufnahmen kam hier der Erfassung der ganzen, bis in den Oktober wirksamen Ablationsperiode zustatten. Die Zwischenablesungen auch an diesen Bojen zeigen, dass die Ablation erst im August wirksam wurde. Für alle Details sei auf den Bericht¹⁾ selbst verwiesen.

Einzelne bemerkenswerte Niederschläge.

Aus Pflicht und Interesse berichtet der Verfasser auch dies Jahr wieder über die „grossen“ Niederschläge des Jahres. Die Pflicht gebietet dabei, alle Niederschläge von einer bestimmten Grössenordnung wenigstens zu erwähnen, auch wenn sie meteorologisch nichts Bemerkenswertes oder gar Neues bieten. Das Interesse kommt der Betrachtung derjenigen Wetterlagen zugute, die dem Meteorologen aus irgend einem Grunde bemerkenswert erscheinen. Die täglichen Wetterberichte erlauben ja selten eine genügend scharfe Diagnose einer Situation zu geben, da im Momente ihrer Abfassung nicht alle Beobachtungstatsachen bekannt sind, und das Vorhandene bei der knappen zur Verfügung stehenden Zeit auch nicht immer in wünschenswertem Masse gewürdigt werden kann. Da sind die folgenden nachträglichen Betrachtungen wenigstens in einigen Fällen eine nützliche Ergänzung, um so mehr als sie eigentlich die einzige Verarbeitung des schweizerischen meteorologischen Beobachtungsmaterials nach dieser Richtung darstellen. Das mag erklären, warum gelegentlich auch von Gesichtspunkten aus diskutiert wird, die man nicht von vornherein in diesem Zusammenhang erwartet. — Bedauerlich ist, dass nicht mehr — wie in früheren Jahren — auf die systematische Zusammenstellung der Gewittermeldungen zurückgegriffen werden konnte, da diese bis zur Zeit der Drucklegung noch nicht vorlagen.

6./7. März.

Starke Ueberregnung der nördlichen Alpenkette am 6./7. März. Am 6. März begann es in den ersten Nachmittagsstunden in unserem Lande zu regnen; es war der Präfrontalniederschlag der warmen Front einer von Nordwesten in den Kontinent eindringenden Depression. Vom 6. auf den 7. März wurde es dabei bedeutend wärmer; es ist in diesem Falle nicht leicht, den Zeitpunkt festzulegen, in welchem die warme Front das Alpengebiet erreichte; auf dem Säntis trat die Haupterwärmung schon am 6., auf dem St. Gotthard zwischen Morgen- und Mittagbeobachtung des 7. ein. Schon bis zum Morgen des 7. wurden in einigen nord-alpinen Talschlüssen grössere Mengen gemessen: Braunwald 54, Auen/Linthal 67, Bisistal 59, Unterschächen 49, Färnigen 64, Gadmen 44 $\frac{m}{m}$. Allgemein erreichten dann im Alpengebiet die Niederschläge für die Jahreszeit grosse Beträge am 7. März, wo bei starken südwestlichen Winden der im Westen liegende Hochdruck gegen Zentraleuropa vorzustossen begann. Dabei war die Druckzunahme bis zum Niveau von Jungfraujoch hinauf genau gleich gross wie im Flachland, also — was auch aus den Temperaturen hervorgeht — nicht thermisch bedingt. Die Tagesmengen vom 7. Mai überstiegen in der ganzen nördlichen Hauptkette 30 $\frac{m}{m}$ und betrugen beispielsweise in Langwies 42, Seewis i. Pr. 42, Sedrun 42, Braunwald 43, Isental 40, Gadmen 68, Andermatt 50, Beatenberg 51,

Jaun 47, Leysin 39 $\frac{m}{m}$, und sogar im Wallis wurden in Reckingen 46, in Leukerbad 47 $\frac{m}{m}$ gemessen. Auch im Jura wurden ähnliche Beträge erreicht: St. Sulpice 42, Mt. Soleil 39 $\frac{m}{m}$.

18. März.

Juraregen vom 28. März. Bereits am 27. März bedingte eine Kanaldepression im Westen und Norden unseres Landes kräftige Niederschläge; die von Westen vordringende Okklusion lag um 13^h noch westwärts des Jura, um 18^h bereits am Bodensee. Viel bedeutender aber waren die Niederschläge, die am 28. März im Neuenburger- und Berner-Jura niedergingen (vergl. Kärtchen 1): La Brévine 40, Fontainemelon 39, Les Brenets 43, La Chaux-de-Fonds 55, Saignelégier 39 $\frac{m}{m}$. Die Wetterkarten zeigten für diesen Tag die Bildung einer vom Hauptminimum — über dem Ozean im Westen von Frankreich — ausgehenden Teildepression in Südfrankreich.

19. April.

Niederschläge vom 19. April in Graubünden. Vom Morgen des 18. bis zum Morgen des 19. April verpflanzte sich ein Depressionszentrum vom Kanaleingang zum Skagerrak unter Bildung eines Teilminimums am Südfuss der Alpen, das am Morgen des 20. in sehr ausgeprägter Form über Ober-Italien lag. Schon vom Nachmittag des 18. an fielen in der Westschweiz — abends 18^h ging die Okklusion durch Zentralfrankreich — beträchtliche Niederschläge; diese erreichten dann am 19. bei der Passage der Okklusion im zentralen und südlichen Bünden grosse Mengen. Es wurden für den 19. gemessen in Splügen 54, Andeer 43, Thusis 47, Inner-Ferrera 50, Nisellas-Alvaschein 52 $\frac{m}{m}$, Beträge, die für diese relativen Trockentäler als recht ansehnlich bezeichnet werden müssen. Auch das Oberengadin hatte grosse (St. Moritz 39 $\frac{m}{m}$), die bündnerischen Südtäler noch grössere Mengen (Misox 63, Braggio 75 $\frac{m}{m}$). — Der Säntis zeigte am 19. April um 17^{1/2}^h scharfen Einsatz von Nordwestwind mit Temperatursturz; auf dem Gotthard setzte der Windwechsel von Süd- zu Nordwind erst nach der Abendbeobachtung (der Temperaturrückgang allerdings vorher!) ein. Auch Jungfraujoch scheint um diese Zeit von der Kaltluftmasse erreicht worden zu sein; am Abendtermin wurde bereits NW-Wind beobachtet; der Temperatursturz trat in der Hauptsache erst nachher ein (21^{1/2}^h -8.7, 7^{1/2}^h morgens des 20. April -14.9 bei WNW₄).

24./25. April.

Die Niederschläge vom 24./25. April, welche die grössten Tagesmengen im oberen Wallis und seinen südlichen Seitentälern erreichen, gehen auf eine meteorologisch recht interessante Situation zurück. Eine ungewöhnlich tiefe Mittelmeerdepression bewegte sich nämlich vom 24. auf den 25. April auf direkt nördlicher Bahn über die Alpen: Zentrum am 24. April 8^h

über Tunis, 19^h westlich von Sardinien und Corsica (Ajaccio 741 $\frac{m}{m}$); am 25. morgens lag neben einem Zentrum über der Rhonemündung ein gleich tiefes, umfangreicheres nordwärts der Alpen (Dijon-München). — Die Annäherung der Mittelmeerdepression machte sich in der Höhe schon am 24. deutlich bemerkbar durch Auffrischen der südöstlichen Luftströmung auf Jungfraujoch, Gotthard und Säntis, auf welch letzteren sie morgens 1^h mit scharfer Drehung des Windes (vorher NE) erst einsetzte. Sie hielt überall an bis in die Nacht vom 25. auf den 26. April und trat vom frühen Morgen des 25. an auch in den nördlichen Alpentälern als Föhn auf, als sich mit der Ausbildung des nordalpinen Minimums ein Süd-Nordgradient über den Alpen entwickelt hatte. Gleichzeitig setzten auf der Alpensüdseite starke Niederschläge ein, die wie öfters über den Kamm herübergriffen (vergl. Kärtchen 2); namentlich das Wallis hatte bis zum Morgen des 25. sehr grosse Beträge: Fiesch 50, Binn 62, Saas-Fee 54, Zermatt 43, Bagnes 54, Bourg-St. Pierre 50, Orsières 40 $\frac{m}{m}$. Im Tessin hielten die Niederschläge auch am 25. den ganzen Tag an und erreichten erst an diesem Tage die maximalen Beträge (Ponte Tresa 85, Brissago 63 $\frac{m}{m}$), als sich die erwähnte Südföhnphase ausgebildet hatte.

Die ungewöhnliche Depressionsbahn gab Veranlassung mit Rücksicht auf Untersuchungen, die H. von Ficker angestellt hat — „Der Einfluss der Alpen auf Fallgebiete des Luftdruckes und die Entstehung von Depressionen über dem Mittelmeer“ (Met. Z. 1920) — die Druckänderungen auf Tal- und Bergstationen in dieser, den betrachteten Fällen in gewissem Sinne umgekehrten Situation zu vergleichen. Geht man vom tiefsten auf dem Jungfraujoch um 7^{1/2}^h des 25. April beobachteten Drucke aus, so ergeben sich für die nächsten 24 Stunden

m	Δb beob.	Δb für das betr. Niveau berechnet nach Δb Jungfraujoch	Δt
3454 Jungfraujoch	5.9 $\frac{m}{m}$	— $\frac{m}{m}$	-2 ⁰
2103 St. Gotthard	6.2 „	5.8 „	0 ⁰
1610 M ^{te} Generoso	7.0 „	7.5 „	-1 ⁰
276 Lugano	8.9 „	8.8 „	-1 ⁰
2500 Säntis	5.7 „	6.7 „	0 ⁰
1787 Rigi	8.6 „	7.2 „	-4 ⁰
277 Basel	12.4 „	8.8 „	-3 ⁰

Auf der Südseite der Alpen sind in allen Niveau die 24 stündigen Druckänderungen ungefähr die nach der Aenderung auf Jungfraujoch berechneten, also die primären. Auf der Nordseite sind sie — wenn wir vom Säntis absehen — grösser und zwar in Basel wesentlich grösser als auf dem Rigi; es addiert sich also eine thermische Druckwelle. Damit stimmt auch der Sinn der Temperaturänderungen, welche für die unteren Schichten der Alpennordseite ein Kälterwerden nachweisen. — In einigen andern Fällen von Verschiebung von Depressionen süd-nordwärts über die Alpen ergab sich auch für den Südfuss ein etwas grösserer Druckanstieg als

der nach Jungfraujoch berechnete, was auf Kälterwerden der dazwischen liegenden Luftsäule schliessen lässt; stets aber war der Druckanstieg am Nordfuss noch grösser. Nur einmal (30./31. Mai 1923) hatte der Nordfuss wesentlich kleineren Druckanstieg als der Südfuss (und auch als Jungfraujoch) als — veranlasst durch eine neue Depression über Westfrankreich — eine rasche Erwärmung eingetreten war.

6. Mai.

Niederschlagsmaxima in der zentral- und ostschweizerischen Voralpenzone vom 6. Mai. In einer umfangreichen, den ganzen Kontinent bedeckenden Depression, bestanden am 6. Mai zwei Zentren nördlich (Westdeutschland) und südlich der Alpen (Poebene). Die Verschiebung des ersteren nach Böhmen auf den 7. Mai brachte einen vorübergehenden thermisch bedingten Vorstoss des westlichen Hochdruckes, der sich in der typischen Keilform über das westliche Zentraleuropa an die Alpen legte. Die Niederschläge wurden am späteren Nachmittag am Nordfuss der Alpen intensiver und erreichten in der zentralschweizerischen Randzone die grössten Beträge: Morgarten 42, Zug 41, Schönenberg 57, Sihlwald 49, Dietikon 44, Sternberg 40, Wald 48, Wesen 49 $\frac{m}{m}$. Die kalten Luftmassen erreichten Zürich um 17^{1/3}^h, den Rigi vor der Abendbeobachtung (21^{1/2}^h); auf dem Säntis drehte der Wind um Mitternacht nach WNW, der Temperaturfall war aber schon vorher eingetreten. Bis zum Morgentermin war die kalte Luft auch über Jungfraujoch emporgewachsen; auf der Alpensüdseite wehte nun heftiger Nordföhn.

15./16. Mai.

Vom 15. auf den 16. Mai fielen am Alpensüdfuss und in der Südwestschweiz grosse Niederschläge. Die Ausgangssituation war eine Furche niedrigen Druckes, die sich am Morgen des 15. von der südlichen Ostsee quer durch den Kontinent nach dem westlichen Mittelmeer zog. Westlich der grossen, vor den Alpen und über dem Rhonetal liegenden Konvergenzlinie flossen kalte Luftmassen aus Norden gegen das Mittelmeer, östlich davon bestand eine warme Luftströmung aus Südosten. Ein über dem westlichen Mittelmeer auftretendes primäres Fallgebiet fand so die geeigneten Bedingungen für die Ausbildung einer ausgesprochenen Depression, die am Morgen des 16. ihr aussergewöhnlich tiefes Zentrum (Ajaccio 740 $\frac{m}{m}$) am Nordufer des Mittelmeeres hatte und sich dann senkrecht zu dem starken, über dem Kontinent bestehenden ostwestlichen Temperaturgefälle nordwärts über das Alpengebiet weiter bewegte. Diese letztere Phase hat Ähnlichkeit mit der oben beschriebenen Situation vom 24./25. April, und es sei in diesem Zusammenhang bemerkt, dass die der Depression nachfolgende Druckzunahme vom 16. auf den 17. Mai nun auch am Alpensüdfusse (Lugano) merklich grösser war, als die nach Jungfraujoch berechnete, da die Luftsäule

zwischen Alpensüdfuss und Kamm eine beträchtliche Abkühlung erfuhr, sich also eine thermische Druckstufe addierte.

Die grössten Niederschläge am Südhang der Alpen fielen auf Schweizergebiet allerdings in der ersten Phase — als der tiefste Druck noch über dem Mittelmeer lag — vom Nachmittag des 15. bis zum Morgen des 16. Mai. Schon am Vortag hatte der Südfuss grosse Tagessummen gehabt (Locarno 100, Crana-Torricella 107, Camedo 133, Brissago 162 $\frac{mm}{m}$). Am 15. nun (vergl. Kärtchen 3) wurden 100 $\frac{mm}{m}$ sozusagen auf allen tessinischen Stationen erreicht (oder beträchtlich überschritten, wie in Ponte Tresa 140, Camedo 228, Mosogno 175, Cevio 176, Locarno 142 $\frac{mm}{m}$); aber auch die östlicher gelegenen bündnerischen Südtäler, in welchen sonst die Niederschläge merklich weniger ergibig zu sein pflegen, stehen diesmal nicht zurück: Le Prese 132, Vicosoprano 119 $\frac{mm}{m}$, und sogar das Engadin weist annähernd dieselben Mengen auf: Sils-Maria 91, Bevers 90, Scarl 86 $\frac{mm}{m}$. Auch nordwärts des Hauptkammes kamen noch enorme Tagessummen vor (Splügen 170, Sedrun und Platta 98, Andeer 106, Savognin 85, Lenzerheide 89, Andermatt 126, Göschenen 100, Guttannen 69, Reckingen 90, Fiesch 110, Saas-Fee 90, Grächen 80 (!), Bourg St. Pierre 71 $\frac{mm}{m}$, während sie dann nach Norden sehr rasch abklingen und in der Nordostschweiz sozusagen kein Regen fiel (St. Gallen und Säntis o!). Dagegen hatte das untere Ende des Genfersees relativ grosse Mengen: Genf 34, Athenaz 45 $\frac{mm}{m}$, wie auch westwärts des Jura sehr reichliche Niederschläge fielen (Dijon 31, Lyon 42 $\frac{mm}{m}$); hier handelte es sich um das Aufgleitregengebiet, das sich mit der Wanderung der Depression nach Norden verschob und am 16. in Westdeutschland grosse Niederschläge brachte.

29. Mai.

Der 29. Mai hatte grosse Niederschlagsmengen in den nordalpinen Tälern: Adelboden 43, Gadmen 57, Interlaken 42, Einsiedeln 45, Ober-Iberg 55, Oberkirch 44, Braunwald 68, Klönthal 59, Obstalden 42, Wallenstadt 48 $\frac{mm}{m}$, dann aber auch im äussersten Norden des Landes: Unter-Hallau 54, Kalchrain 54, Eschenz 43, Amriswil 45, Sulgen 45, Müllheim 51 $\frac{mm}{m}$. Die Hauptmengen dieser für die flache Nordostschweiz ausserordentlichen Niederschläge wären beurteilt nach dem Zürcher Registriardiagramm in den frühen Morgenstunden des 30. Mai gefallen; es finden sich aber für den 29. Mai nachmittags und abends einzelne Gewittermanifestationen notiert (Horgen, Aadorf, Kalchrain), so dass die eben genannten Maximalbeträge der Nordostschweiz durch Gewitterregen vom Vormittag mitbedingt scheinen. Im übrigen lassen sich keine klaren Beziehungen dieser Niederschläge zu Diskontinuitätslinien herauschälen. Es sei daher nur allgemein bemerkt, dass an diesem Tage am SE-Rand eines zwischen Island und Schottland gelegenen Tiefs sich sekundäre Wirbel ostwärts bewegten. In Zürich begann der Regen bei leichtem Barometer-

anstieg um 17 $\frac{1}{2}$ ^h, der Hauptniederschlag erfolgte bei schwach sinkendem Barometer, wobei auf dem Säntis der sonst anhaltende und kräftige NW-Wind in Windstille überging.

3. Juni.

Am 3. Juni erreichten die Niederschläge in der Nordostschweiz aussergewöhnliche Beträge: Heiden 65, Rorschach 57, Amriswil 44, Sulgen 45, Müllheim 56, Affeltrangen 43, Schaffhausen 41, Fehraltorf 39 $\frac{mm}{m}$. Sie sind in der Hauptsache nach Mitternacht des 3./4. Juni gefallen. Diese am 4. Juni morgens 7 $\frac{1}{2}$ ^h gemessenen Beträge stellen nur einen Teil der Niederschlagsmengen dar, welche die zu betrachtende Wetterphase brachte, da sie am 4. Juni untertags noch anhielten. Am 3. Juni lag eine flache ostwärts wandernde Depression über Ostfrankreich; auf ihrer Rückseite war kalte Luft an den Alpennordfuss gelangt, so dass beträchtliche Temperaturgegensätze gegen das deutsche Küstengebiet bestanden: Zürich 8°, Wilhelmshaven 15°; noch wärmer war es in Ostpreussen und im Baltikum: Königsberg 20°, Riga 21°. Diese Temperaturverteilung ist charakteristisch für die grossen nordalpinen Frühsommerregen (vergl. z. B. 10./12. Juni 1876, 19./20. Mai 1906). Die Verlagerung des Druckminimums nach Böhmen auf den 4. Juni brachte nun bei der zyklonalen Zirkulation relativ warme und feuchte Luft an den Alpennordrand, wo sie über die noch fortbestehende Kaltluftschicht (Zürich 7°, München 6°) am Morgen des 4. Juni aufglitt und die starken Niederschläge im Alpenvorlande bedingte. Als Luftbewegung in der Höhe wird vom Rigi NW-Wind Stärke 2, vom Säntis leichter WSW angegeben. Die Temperaturen betrugen am Morgen des 4. Juni nach dem Lindenberger Aufstieg in 1700 m Höhe 5.5°, auf dem Rigi (1787 m) dagegen -1.8°, in 2200 m über Lindenberg 1.2° gegen -6.0° auf dem Säntis (2500 m).

13. Juni.

Der 13. Juni brachte dem Kanton Graubünden grosse Niederschläge, welche namentlich in den sonst relativ niederschlagsarmen inneren Tälern ausserordentliche Beträge erreichten: Safienplatz 44, Avers-Cresta 52, Inner-Ferrera 75, Andeer 50, Thusis 54, Savognin 68, Davos 53, Filisur 56, Nisellas 74, Lenzerheide 84, Arosa 64, Langwies 63, Klosters 41 $\frac{mm}{m}$. Sie wurden verursacht durch einen Kaltlufteinbruch auf der Rückseite einer Teildepression, die am Morgen des 13. vor der niederländischen Küste, am Morgen des 14. über Norddeutschland lag; auf den 14. hatte sich eine sekundäre Depression über Oberitalien gebildet. Niederschlag fiel in Zürich am frühen Nachmittag des 13. (von 1 $\frac{3}{4}$ ^h bis 17 $\frac{1}{2}$ ^h), nachdem der Druck schon am Morgen (8 $\frac{3}{4}$ ^h) zuzunehmen begonnen hatte mit gleichzeitiger Winddrehung nach NW; der Hauptanstieg setzte 12 $\frac{1}{2}$ ^h ein mit scharfem Temperaturfall. 15 $\frac{1}{2}$ ^h war bereits das Säntisniveau erreicht, wo um diese Zeit der Wind auffrischte und von SW nach W zurückdrehte. Auf Jung-

fraujoch dagegen ergab die Abendbeobachtung (18^{1/2}^h) noch SSE-Wind und gleiche Temperatur wie am Mittag; erst aus der Morgenbeobachtung des 14. ist hier der Temperaturfall und die NW-Drift ersichtlich. Der Niederschlag setzte in Landquart um 16^h, in Davos und Arosa um 17^{1/2}^h ein, und es fiel bis zum Abendtermin (21^{1/2}^h) ein schwacher Drittel der oben genannten Mengen; in der Nacht ging der Regen bis gegen 1200 m herab in Schnee über. Arosa meldet von 21^{1/2}^h Elmsfeuer und 23^h und 2^h (14.) stille Entladungen; sonst beschränkten sich die Gewittererscheinungen auf die Alpensüdseite.

19. Juni.

Bei den sehr intensiven Niederschlägen, die am 19. Juni auf der nördlichen Abdachung der Alpen fielen, wiegt der Geländeregencharakter vor (vergl. Kärtchen 4). Die Böenlinie einer Depression über den Niederlanden und Westdeutschland passierte am Vormittag des 18. Juni unser Land und schon dieser Tag hatte unter Gewittererscheinungen lokal grosse Tagesmengen, so in der Zentralschweiz und im Bachtel- und Rickengebiet (Sattel 53, Rigi 42, Euthal 42, Bachtel 51, Wald 50, Hinwil 47, Sternenbergr 40, Ricken 42, Starkenbach 42 ^{mm}). Die am 18. Juni auf dem Säntis und dem Rigi den ganzen Tag über beobachtete NW-Strömung trat in Zürich erst in der Nacht vom 18./19. (3^h a) mit dem stärkeren Barometeranstieg auf und verlor auf den genannten Höhenstationen gleichzeitig an Stärke. Der reine NS-Verlauf der Isobaren über Zentraleuropa (der tiefste Druck lag nur über Ober-Italien und Ungarn bei von Westen vorstossendem Hochdruck) lässt keinen Zweifel an der Natur dieses an keine Front gebundenen nordalpinen Regens, der nach Westen und Norden rasch abnahm (Genf 0,3, Schaffhausen 0,2 ^{mm}!), in der nördlichen Hauptkette ostwärts der Aare aber sehr intensiv war: Guttannen 52, Gaden 58, Andermatt 51, Altdorf 62, Isenthal 78, Rickenbach 68, Weggis 51, Engelberg 64, Walchwil 48, Hausen a. A. 41, Euthal 86, Oberberg 60, Bachtel 50, Lachen 62, Weesen 70, Klönthal 64, Wallenstadt 59, Starkenbach 65, Peterzell 68, Degersheim 45, Urnäsch 44, Valens 51, Haag 42, Plantahof 45 ^{mm}.

22. Juni.

Die am 22. Juni in verschiedenen Gebieten lokal auftretenden sehr grossen Niederschläge fielen bei Gewittern. Es passierte in den Nachmittagsstunden dieses Tages die Böenlinie einer über Sachsen gelegenen Teildepression unser Land. Die grössten Niederschläge fielen im Waldenburger Tale und Umgegend (Seewen 55, Lampenberg 70, Waldenberg 62, Diegten 73, Eptingen 64, Langenbruck 81, Balsthal 74, Olten 54 ^{mm}); aber auch ostwärts davon kamen lokal ähnliche Beträge vor: Rheinau 46, Unter-Hallau 46 (dagegen Schaffhausen 3 ^{mm}), Winterthur 46, Kollbrunn 42, Eschlikon 46, Aadorf 63, Flawil 51, Müllheim 42, Altnau 42, Arbon 56, Rorschach 53 ^{mm}; in der voralpinen Zone hatten die grössten

Tagesmengen Klönthal 44 ^{mm}, dann das Pilatusmassiv (Sarnen 52, Pitatus-Kulm 94 und Buchsteg 71), Brienz 64, Beatenberg 40, Heiligenschwendi 64 (dagegen Thun 41), Jaun 40 und Vouvry 39 ^{mm}).

2. Juli.

Im Juli kamen am 2. in Sevelen (54 ^{mm}) und am 4. in Vrin (50 ^{mm}) ganz lokale Platzregen vor. Etwas grössere Ausdehnung hatten die ergibigen Gewitterregen vom 5. im Basler Jura (Kilchberg 52, Eptingen 69, Lampenberg 55, Reigoldswil 43, Weissenstein 50 ^{mm}).

7. Juli.

Weit verbreitet waren dann die intensiven Niederschläge vom 7. Juli (vergl. Kärtchen 5). Ausser dem Tessin, wo Tagesmengen bis zu 100 ^{mm} (Mte. Generoso 106, Camedo 104, Mosogno 94 ^{mm}) fielen, hatte das Wallis ausserordentliche Mengen: Fiesch 74, Saas-Fee 81, Visp 76, Grächen 57, St. Bernhard 77, Bourg St. Pierre 59, Dailly 48, Clarens 39 ^{mm}. Aber auch die Nordseite der Berneralpen zeigt ungewöhnliche Beträge: Eigergletscher 63, Lauterbrunnen 47, Kandersteg 53, Lenk 49 ^{mm}, während östlich der Reuss viel kleinere Mengen fielen (Glarus 11, Chur 2 ^{mm}). Ausser dem westschweizerischen Alpengebiet wurden auch die Voralpen und der Jura im Westen stark überregnet: La Valsainte 47, Marsens 47, Marbach 53, Schwarzenegg 59 ^{mm}; Arisdorf 43, Mervelier 55, Grellingen 45 ^{mm}, und im Norden des Landes setzen sich diese intensiven Beträge noch bis in die Ostschweiz fort: Wilchingen 41, Unter-Hallau 39, Kalchrain 38 ^{mm}. Man kann in diesem Falle nicht von einem frontalen Regen sprechen und muss sich begnügen mit der Konstatierung dieser Maximalzonen. Die Wetterkarte vom 7. Juli zeigte ein flaches sich ausfüllendes Minimum über Süd-England, während eine andere Depression im Süden der Alpen sich auf den 8. vertiefte. In der Höhe ging Südwind, der auf Jungfraujoch auch noch am 8. zu konstatieren war, auf dem Säntis am Abend des 7. nach NE gedreht hatte.

14. Juli.

Ganz vereinzelt kamen grosse Niederschläge vor bei den Gewittern vom 14. Juli (Buchsteg 50 ^{mm}) und 15. Juli (Wilchingen 44, Buchsteg im Eigenthal 65 ^{mm}).

19. Juli.

Ausgedehnter waren die von Gewittern begleiteten Niederschläge vom 19. Juli. Schon am 18. war es auf der Vorderseite einer westlich von Frankreich gelegenen Depression über Mitteleuropa sehr warm geworden. Die Passage einer Konvergenzlinie dieser Depression — die am Morgen des 19. ihr Zentrum über den britischen Inseln hatte — brachte unserm Lande am Morgen des 19. nur ganz schwachen Regen. Darnach heiterte es auf und wurde mittags wieder sehr warm. Die am Nachmittag dann auf der Nordseite der Alpen allgemein einsetzenden Gewitter müssen in Verbindung gebracht werden mit der

Passage der Böenlinie einer am Morgen des Tages über Holland gelegenen Teildepression. Die durch den Einbruch kühler Luftmassen aus Westen dabei auftretende Abkühlung war in Säntishöhe um so beträchtlicher, als ihr seit dem Abend des 18. eine Föhnphase vorangegangen war. (Tagesmittel vom 20. auf Säntis 9.0° kälter als am 19. Juli, auf Jungfrauoch nur 3.7°). Die gemessenen Niederschläge (vergl. Kärtchen 6) ergaben die grössten Beträge im zentral- und ostschweizerischen Voralpengebiet: Beatenberg 59, Wimmis 60, Schwarzenegg 58, Escholz matt 58, Unter-Kulm 58, Weggis 59, Rigi 70, Stans 59, Sarnen 55, Luzern 53, Zug 74, Sihlwald 58, Pfannenstiel 56, Küsnacht 47, Vorder-Wäggital 50, Uster 44 $\frac{m}{m}$.

27. Juli.

Der 27. Juli brachte unserm Lande einen Wettersturz mit sehr fühlbarer Abkühlung. Auf der Rückseite einer über Schweden liegenden Depression — eine flache Depression lag über Oberitalien — drang kalte Luft aus N bis zu den Alpen vor. Säntis und Jungfrauoch scheinen um die Mittagsbeobachtung davon erreicht worden zu sein; die zu dieser Zeit einsetzenden Niederschläge ergaben (vergl. Kärtchen 7) in der Osthälfte der nördlichen Hauptkette grosse Beträge: Isenthal 44, Sattel 54, Gersau 52, Rigi 54, Euthal 53, Weesen 52, Appenzell 61, St. Gallen 52, Teufen 56 $\frac{m}{m}$. Eine zweite Maximalzone findet sich in Graubünden, vom Avers bis nach dem St. Antönienthal sich erstreckend: Safienplatz 45, Andeer 46, Thusis 44, Inner-Ferrera 61, Lenzerheide 58, Tschiettschen 50, St. Antönien 50, Klosters 41 $\frac{m}{m}$. Bis ca. 1300 m herab fiel dabei Neuschnee. — Mit dem Kaltlufteinbruch südwärts der Alpen sind wohl die am Nachmittag dort ausbrechenden Gewitter in Verbindung zu bringen. — Verwunderlich gross sind die Tagesmengen vom Nachtag von Wildhaus 41, Starkenbach 89 und Teufen 41 $\frac{m}{m}$; auch der Säntis hatte noch 55 $\frac{m}{m}$.

7. August.

Am Morgen des 7. August lag eine flache Depression über der südlichen Nordsee; von ihr aus zog sich eine Regen- und Gewitterfront mit kühlerer maritimer Westluft auf der Rückseite südwärts. Uccle meldete die erste Störung morgens 3^h ; es darf angenommen werden, dass es dieselbe Böenlinie war, die Basel um $8^h/4$ — 10^h , Zürich $11^h/2$ — 13^h den ersten Gussregen brachte, in Zürich verbunden mit NW-Windphase und stärkerem Temperaturfall. Das Barometer fiel aber (nach einer „Gewitternase“) weiter, und der Nachmittag brachte wieder Regen, in Zürich sehr intensiv bei dem Gewittervorübergang um $18^h/4$, wo auch der Barometeranstieg einsetzt. Die in der Zentral- und Nordostschweiz starken Gewitterregen erreichten die grössten Intensitäten im Entlebuch (Escholz matt 43, Flühli 51), am Pilatus (Buchsteg 50, Stans 44 $\frac{m}{m}$), zwischen Vierwaldstättersee und Zürichsee (Küsnacht 41, Rickenbach 44, Lorzetobel 42, Schönenberg 56,

Euthal 41 $\frac{m}{m}$), am Bachtel (Hinwil 45 $\frac{m}{m}$) und am Ricken (Oberkirch 40, Ricken 52, Ebnet 51, Degersheim 44 $\frac{m}{m}$).

11. August.

Am 11. August brachte die Passage der Okklusion einer über der Nordsee liegenden Depression dem ganzen Lande Niederschläge, die diesmal im Westen am intensivsten waren (Genf 31, Lausanne 34, Zürich 16 $\frac{m}{m}$). So wurden im allgemeinen in der nördlichen Alpenkette westwärts der Aare die grössten Beträge erreicht: Martigny 47, Dailly 54, Vouvy 48, Montreux 45, Château d'Oex 47, La Valsainte 47, Lenk 42, Frutigen 51, Brienz 42 $\frac{m}{m}$; immerhin kamen auch ostwärts des Gotthardmassivs in der voralpinen Zone noch vereinzelt solche Tagesmengen vor: Rigi 57, Morgarten 42, Oberkirch 42, Bachtel 44 und Wald 43 $\frac{m}{m}$.

17. August.

Bei den am 17. August auftretenden Gewittern kamen ganz lokal sehr starke Platzregen vor in Wasen i. E. (73 $\frac{m}{m}$) und im Val de Ruz (Fontainemelon 63 $\frac{m}{m}$).

5. und 12. September.

Von dem 3., gleich dem August trockenen September sind erwähnenswert einzelne bei lokalen Gewittern gefallene Gussregen. So diejenigen vom 3. September in Wimmis (40 $\frac{m}{m}$), Schwarzenegg (40 $\frac{m}{m}$), am Rigi (Rigikulm 71, Küsnach 67 $\frac{m}{m}$), in Entlebuch (49 $\frac{m}{m}$). Am 5. September wurden in Sevelen und Plantahof je 40 $\frac{m}{m}$, am 12. September auf Rigi und Sattel je 41 und in Weesen 40 $\frac{m}{m}$ gemessen.

26. September.

Sehr interessant sind die starken Regenfälle vom 26. September im nördlichen und nordwestlichen Teil unseres Landes, mit denen die grosse Trockenheit des Spätsommers ihren Abschluss fand. Am 25. September lag ein Depressionszentrum zwischen Schottland und dem südlichen Norwegen, und es reichte von ihm aus eine scharfe Konvergenzlinie mit einem Regenband über Holland südwestlich abbiegend nach der Loire. Die Schweiz bekam am 25. nur schwachen Regen; erst in den frühen Morgenstunden des 26. wurde er intensiver. Die langsam südwärts vordringenden Kaltluftmassen waren offenbar nur von geringer Mächtigkeit und erreichten knapp unser Land. Ueber ihnen aber setzte zufolge Druckzunahme südwärts der Alpen in der Nacht vom 25./26. eine sich auf allen unsern Höhenstationen manifestierende Südströmung ein. Die am 26. den ganzen Tag anhaltenden Niederschläge erreichten ihre grösste Intensität (vergl. Kärtchen 8) in einer vom Rhoneknie über Freiburg nach Neuenburg reichenden und von hier dem Jurafluss folgenden Zone: Marécottes 61, Martigny 44, Jaun 42, Aarberg 43, Boudry 45, Neuenburg 48, Biel 53, Evilard 49, Weissenstein 41, Solothurn 77, Langenbruck 47, Herzogenbuchsee 41, St. Urban 49, Olten 53, Unter-Kulm 48, Aarau 50, Bötzbegg 43,

Schöfflisdorf 45, Boppelsen 45, Kaiserstuhl 42, Wil b. Rafz 40, Schaffhausen 44, Diessenhofen 40 $^{\text{mm}}$.

21. Oktober.

Nicht weniger Interesse dürfen die Niederschläge vom 21. Oktober beanspruchen, die in der Südwestschweiz besonders intensiv waren (vergl. Kärtchen 9). Zu Ende der zweiten Oktoberdekade bestand über Europa längere Zeit eine scharfe Temperaturgrenze zwischen warmer Tropikluft im Süden und einer in breiter Front aus Norden vordringenden Kaltluftmasse. Am 18. Oktober war unser Land von letzterer erreicht worden, wobei in Zürich die Mitteltemperatur von 14.9° am 17., auf 6.6° am 18. und 4.7° am 19. zurückging (Temperatur dieser drei Tage auf dem Rigi 4.7° , -2.0° , -5.4° , auf dem Säntis 2.0 , -3.9° , -7.0°).

Am 20. Oktober machte sich in der Höhe wieder Erwärmung geltend unter Auffrischen einer starken südwestlichen Luftströmung. Eine nördlich der Azoren liegende Depression gewann gegen den Kontinent an Raum und wies am Morgen des 20. ein Teilminimum über der Gascogne auf. Die auf der Südseite dieser Tiefdruckfurche heranrückende Warmluft begann über die zentraleuropäische Kaltluftmasse aufzugleiten; das Vordringen der Regenfront gegen Norden lässt sich aus den Situationsberichten des „Bolletino meteorico“ von Rom verfolgen, das vom 19. auf den 20. „piogge regioni meridionali“, vom 20./21. „piogge alto versante Tirenico ed Adriatico e regioni centrali“, vom 21./22. „piogge abbondanti regioni settentrionali, alto Adriatico e Tirenico“ feststellt. In der Schweiz begann es am Nordfuss der Alpen früher zu regnen (ca. um 22^{h} des 20. Oktober) als am Südfuss (Lugano erst nach der $7\frac{1}{2}^{\text{h}}$ -Beobachtung des 21. Oktober); in diesem Falle wirkt ja nicht nur die Alpenmauer, sondern auch die Kaltluftmasse nördlich derselben als niederschlagsbedingend und die Wirkung der Front verstärkend.

Die Niederschläge fielen am 21. Oktober in der Westschweiz ohne Unterlass und sehr ergibig. Die Morgenkarte zeigte das Druckminimum über der Biscayasee mit einem Ausläufer gegen den Nordfuss der Alpen. Es verlagerte sich bis zum Morgen des 22. Oktober senkrecht zum Temperaturgradienten, also ostwärts, nach Böhmen. Auf seiner Rückseite drang über Frankreich kalte Luft bis zum Mittelmeer vor, was Veranlassung gab zur Ausbildung einer Zyklone über dem Golf du Lyon. Die Aufgleitregen längs der europäischen Polarluftfront erreichten damit im Gebiet der Westalpen und der Südwest- und Westschweiz ihre maximale Intensität: Genf 43, Lausanne 59, Yverdon 61, Baulmes 54, Moudon 52, Payerne 52, Boudry 39, Evillard 41, Aarberg 38, Romont 42, Vouvry 37 und Leysin 47 $^{\text{mm}}$.

23. Oktober.

Die Niederschläge hielten — weniger ausgiebig und mit Unterbrüchen — auch an den folgenden Tagen an,

da die Rinne niedrigen Druckes, die sich west-ostwärts durch den Kontinent zog und eine scharfe Scheidung zwischen den kalten Luftmassen auf ihrer Nordseite und der Tropikluft im Süden darstellte, weiter bestand. Am 23. Oktober fielen im bündnerischen Rheingebiet und den angrenzenden Tälern wieder grosse Mengen. Veranlassung dazu gab eine Vertiefung des Druckes unmittelbar südwärts der Alpen im Laufe dieses Tages; die italienische Wetterkarte zeigt für den Morgen des 24. Oktober ein Minimum von 741^{mm} über der unteren Poebene und Triest. Die Ausbildung dieses Minimums bedingte am Nachmittag des 23. ein Drehen des Windes über den Alpen nach Norden verbunden mit Temperaturfall (Zugspitze, Gotthard; dagegen behielt Jungfraujoch die südliche Windströmung, wenigstens nach den vorhandenen Terminbeobachtungen, trotzdem auch hier die Temperatur in der Nacht um den gleichen Betrag zurückging). Der Regen setzte im Bündnerland in den ersten Nachmittagsstunden ein und ging in der Nacht bis gegen 1000 m herab in Schnee über. Die maximale Niederschlagszone (vergl. Kärtchen 10) umfasst das Gebiet des Vorder- und Hinterrheins (Vrin 60, Safienplatz 60, Avers-Cresta 56 $^{\text{mm}}$), aber auch am Nordfuss der Urner/Glarnerkette (Bisisthal 43, Linthal 39, Weisstannen 46, Planta-hof 41) und noch südlich der Hauptkette (Olivone 49, Soglio 40 $^{\text{mm}}$) fielen grosse Beträge.

29. Oktober.

Der Schluss des Monats brachte noch einmal starke Niederschläge. Zunächst am 29. Oktober, wo auf der Alpennordseite der Neuenburger Jura die Maxima hatte (Fontainemelon 40, Chambrelieu 43 $^{\text{mm}}$); aber auch im Südosten des Landes fielen grosse Mengen (Cavaglia 93, Le Prese 61, Vicosoprano 58, Sils-Maria 48, St. Maria i. M. 41 $^{\text{mm}}$). Aus den Wetterkarten ist ersichtlich, dass sich an diesem Tage ein Sektor warmer Luft auf der Südseite einer sich von der Bretagne gegen die Ostsee ziehenden Tiefdruckfurche keilartig über Deutschland in den Kontinent hineinschob; Niederschläge fielen an seiner nördlichen Begrenzung (am Kanal), wie auch an seinem Südrande über dem Alpengebiet.

31. Oktober.

In der Folge zog sich die warme Luft südwestlich zurück, da auf der Rückseite einer sich aus der genannten Tiefdruckrinne nach Finnland verschiebenden Depression die im Norden lagernde kalte Luft bis nach Mitteleuropa gelangte. Am 31. Oktober zeigte die Wetterkarte eine Okklusion von Esthland bis nach Zentralfrankreich; die quasi-stationäre Grenze der warmen und kalten Luft aber verlief an diesem Tage etwa von Oran über Barcelona nach Zentralfrankreich, bog südwärts um die Westalpen aus, und folgte dann dem Laufe des Po. Ueber Frankreich und dem östlichen Spanien bestand eine Depression, die im Laufe des 31. Oktober etwa parallel zur Temperaturgrenze sich ost-nordostwärts nach

dem Weichselgebiet fortpflanzte. Auf der Nordseite der Alpen hatte sich schon seit der Nacht des 30./31. Oktober Föhn eingestellt, der bis gegen Abend des 31. anhielt. Südwärts der Alpen fiel der Aufgleitregen der Warm-Front, am Südhang des Gebirges verstärkt durch die Geländewirkung und es kamen unter vielfachen Gewittererscheinungen enorme Tagesmengen vor. Die 100 mm -Isohyete umschliesst (vergl. Kärtchen 11) fast den ganzen Kanton Tessin, ferner das Medelserthal (Platta 114), das Rheinwald (Bernhardin 165, Splügendorf 111), das Bergell (Vicosoprano 143) und auch im Engadin fielen ausserordentliche Mengen (Sils 70). Die Maxima mit über 200 mm haben die oberen Täler am Langensee (Mosogno 227, Camedo 220, Sonogno 204 mm). — Am Abend hatte sich die Grenze der warmen Luft unmittelbar an den Alpensüdfuss herangeschoben; Lugano und mit ihm das ganze untere Tessin notierte bei der Abendbeobachtung (21 $\frac{1}{2}$ h) 18.2° bei stärkstem Südwind. Schon im Laufe des Tages war er in höheren Lagen sturmartig aufgetreten, so in Braggio, wo er seit morgens 3h ging und Bäume entwurzelte. (In diesem Falle wäre der von L. Lammert für die Südseite der Alpen wahrscheinlich gemachte Wirbel mit horizontaler Axe, der eine absteigende Luftbewegung, also N-Wind, am Hange selbst postuliert, auch in der Höhe von Braggio [1300 m] nicht vorhanden).

2. November.

Noch in Verbindung mit der soeben erwähnten mehr oder weniger stationären Lage der warmen Front über Ober-Italien scheinen auch die starken Niederschläge zu stehen, welche die Südostschweiz am 2. November erhielt: Mezzana 63, Lugano 66, Crana-Torricella 87, Sonogno 96, Grono 67, Braggio 79, Olivone 66, Surrhein 56, Vrin 59, Splügen 52, Inner-Ferrera 70, Vicosoprano 52, Cavaglia 55 mm . Wenn man damit die starken Niederschläge zusammenhält, die weiter südlich in Italien an diesem Tage fielen (Mailand 43 mm), so ergibt sich, dass diese Regen nicht nur Geländeregen der SE-Luftdrift an den Alpen sind, sondern eine allgemeinere Ursache haben.

19. November.

Die Niederschläge des 19. November fallen zusammen mit einem ausgesprochenen Temperaturrückgang in der Höhe, an den sich einige interessante Feststellungen knüpfen. Schon die unmittelbar vorausgegangene Wetterphase brachte einen erheblichen Temperaturfall. Am 16./17. November lagen die Temperaturen über dem Alpengebiet ungemein hoch für die Jahreszeit und betrugen z. B. am Morgen des 17. auf St. Gotthard 4.7°, auf Säntis 5.0° und auf Jungfraujoch -0.7°. Das Alpengebiet befand sich am NW-Rand einer sich nach Südost-Europa verlagernden Antizyklone. Bis zum Morgen des 18. frischte dann wegen Ausbildung eines starken SN-Gradienten über den Alpen — Erscheinen einer tiefen Depression vor Irland — südliche Winde auf, welche

diese antizyklonale Temperaturverteilung zerstörten; trotz ihrer südlichen Herkunft erniedrigten sie die Temperaturen der drei genannten Stationen auf 0.2°, 1.2° und -6.3°; nur in den Alpentälern, wo der Föhn ging, stieg die Temperatur auf den 19. noch mehr an. Die Warmluft reichte nach Norden bis zu einer Aufgleitlinie Irland, Dänemark, Südschweden, und überflutete also ganz Mitteleuropa. Bei der west-östlichen Passage der kalten Front der Depression über dem Alpengebiete am 19. — am Morgen dieses Tages war sie etwa durch Calais-Marseille gegangen — setzte nun weiterer Temperaturfall ein, und die drei Höhenstationen notierten am Morgen des 20. November -4.0°, -6.8° und -13.2°. Dabei war aber in den Strömungsverhältnissen über den Alpen nach den Windbeobachtungen unserer Bergstationen keine merkliche Aenderung eingetreten, wenn man absieht von einer Drehung von S auf SW auf dem Säntis um 20 $\frac{1}{2}$ h, die schon um 23 $\frac{1}{2}$ h wieder auf SSW zurückging. Zürich hatte eine kurze NW-Windphase mit Niederschlag am Nachmittag; bei der Abendbeobachtung ging schon wieder SE-Wind.

Dieser erneute Temperaturfall vom 19./20. ohne Winddrehung nach Norden über dem Alpengebiet ist recht bemerkenswert. Offenbar brachte der Vorübergang der Böenlinie über dem Alpengebiet sofort kältere Luftmassen aus W bis über Kammhöhe, und die Abkühlung musste sich nicht wie ein nordsüdwärts fortschreitender Kälteeinbruch vor den Alpen langsam in die Höhe emporarbeiten. Demgemäss hinkt auch der Druckanstieg südwärts der Alpen zeitlich demjenigen auf der Nordseite nur wenig nach: in Zürich erfolgte er zum grösseren Teil in den Nachmittagsstunden des 19. November, in Lugano in den Abendstunden des 19. November. Am Morgen des 20. war der süd-nördliche Barometergradient über dem Alpengebiet schon wieder sehr beträchtlich und die Windbeobachtungen unserer Bergstationen zeigen keinen Unterbruch in der südlichen Luftdrift. — Die Niederschlagsmengen des 19. November erreichten ihr Maximum in der St. Gotthardzone (im weiteren Sinne): St. Gotthard 91, Andermatt 55, Guttannen 67, Oberwald 72, Saas-Fee 51, Airolo 87, Cevio 89, Camedo 155, Mosogno 113, Sonogno 80, Platta 57, Bernhardin 90, Hinterrhein 68 und Vicosoprano 52 mm).

21. November.

Auch die Wetterentwicklung der nächsten Tage war ungemein interessant und brachte am 21. November eine Niederschlagsverteilung in unserem Lande, die nicht ohne weiteres verständlich ist (vergl. Kärtchen 12). Ein schmales Band, das sich von SSW nach NNE quer über die Alpen erstreckt, bezeichnet die Maximalzone dieses Tages mit Maxima von 100 mm nord- und südwärts der Alpen: Mosogno 107, Sonogno 189, Faudo 81, Platta 106, Sedrun 88, Surrhein 90, Auen/Linth 88, Glarus 92, Weesen 81, Obstalden 116, Starkenbach 97, Säntis 76, Schwäbrig 121, Altstätten 81 und Heiden 85 mm .

Der oben erwähnten Abkühlung vom 20. November folgte auf den 21. wieder eine merkliche Erwärmung; die Morgentemperaturen waren auf St. Gotthard 0.0° , Säntis -1.2° und Jungfrauoch -7.7° . Das Zentrum einer neuen Depression hatte sich bis zum Morgen des 21. November nach der Nordspitze Schottlands fortgepflanzt; eine Okklusion dieser Depression ging an diesem Morgen bis nach Mitteldeutschland; von dort an nimmt die belgische Wetterkarte einen warmen Sektor an: die warme Front verläuft vom Oberlauf der Weser ungefähr ostwärts. Die kalte Front hatte Zürich ungefähr 4^h morgens passiert, wo starke Druckzunahme und Auffrischen des NW einsetzt, mittags ist auch München erreicht. Während in den schweizerischen Föhntälern der Föhn vor der Morgenbeobachtung erlosch und gleich nachher intensiver Niederschlag einsetzte, der bis in die Nachmittagsstunden anhielt, hatten die bayerischen Stationen noch bis Mittags ungewöhnlich heftigen Föhnsturm von ver-

heerenden Wirkungen¹⁾. Noch weit draussen über dem norddeutschen Tieflande ist diese warme Strömung in der Höhe zu finden; der Lindenbergaufstieg ergab gegenüber einer Temperatur von 8° am Erdboden 14° , 10° und 6° in den Niveaus von 1000, 1500 und 2000 m. Die enormen Niederschläge in der oben abgegrenzten Zone fielen also vor einem wenig östlich davon noch bestehenden intensiven Föhnstrom. — Auch in diesem Falle brachte die Passage der Böenlinie über dem Alpengebiet nur kurze Unterbrechung der südlichen Luftdrift — auf dem Säntis wurde von 14^{30} — 22^{30} NW-Wind registriert —, dagegen war der Temperaturrückgang (Morgentemperaturen des 22. November auf St. Gotthard -2.8° , Säntis -6.2° und Jungfrauoch -12.2°) ein bleibender.

Dr. R. Billwiller.

Nr. 3.

Gewitterbeobachtungen im Jahre 1926.

(Mit 4 Tafeln.)

Die Gewitterbeobachtungen wurden in gewohnter Weise fortgesetzt und vom unterzeichneten Bearbeiter zusammengestellt. Das nachstehende Verzeichnis gibt die Namen derjenigen Beobachter, welche sich durch Einsendung einer erheblichen Zahl von entsprechend ausgefüllten Rapportkarten, eventuell auch von schriftlichen Mitteilungen, oder wenigstens durch Eintragung einer grösseren Anzahl, mit genauen Zeitangaben versehener Notizen in den Monatstabellen dienstbar gemacht haben.

1. Kanton Aargau.

Aarau — H. Amsler, Werkführer.
Böttstein — H. Erne, Lehrer.
Köllikon — R. Häny, Lehrer.
Möhlly — A. Kramis, Pfarrer.
Rheinfelden — Frau A. Hoffmann.
Zofingen — E. Ott, Postbeamter.
Zurzach — J. Eichenberger, Lehrer.

2. Kanton Appenzell.

Heiden — G. Landolf, Lehrer.
Säntis — P. Steier, Wetterwart.
Teufen — J. Tanner, Lehrer.

3. Kanton Basel.

Augst — E. Halter, Aufseher.
Basel — meteorol. Anstalt Bernoullianum.
Bennwil — Gottlieb Heinemann.
Kilchberg — E. Buess, Landwirt.
Lampenberg — Emil Vögelin.
Langenbruck — T. Bider, Sigrist.
Liestal — H. Pfaff, Aufseher.
Pfeffingen — M. Tschudy, Lehrer.
Reigoldswil — K. Plattner, Sigrist.
Riehen — Dr. W. Strub.
Therwil — A. Stehlin, Bezirkslehrer.
Wintersingen — W. Bührer, Pfarrer.

4. Kanton Bern.

Beatenberg — Franz Rupp, Pfarrer.
Bellelay — C. Winkelmann, Portier.
Bern — Tellur. Observatorium.
Delémont — H. Gobat, insp. scol.
La Ferrière — J. L. Herzog, pasteur.
Guttannen — H. Huber.
Herzogenbuchsee — J. Kaufmann, Lehrer.
Lauterbrunnen — Fr. Gammeter, Sek.-Lehrer.
Mervelier — Ch. Marquis.
Wasen — J. Wiedmer, Sekundarlehrer.

5. Kanton Freiburg.

Freiburg — Dr. A. Gockel, Professor.
La Valsainte — A. Churlet.

6. Kanton St. Gallen.

Altstätten — J. Haltner, Lehrer.
Degersheim — J. Roth, Weibel.
St. Gallen — J. G. Kessler, Bankbeamter.

7. Kanton Genf.

Genf — Observatorium.

8. Kanton Glarus.

Elm — W. Zentner, Stationsvorstand.
Glarus — J. Gehring, Waisenvater.

9. Kanton Graubünden.

Bernhardin — E. Albertini.
Bevers — G. Krättli.
Braggio — C. Berera, Förster.
St^a Maria — S. Tuffli, Zolleinnehmer.
Platta-Medels — Th. J. Berther, Pfarrer.
Seewis — Fr. D. Fopp.

10. Kanton Luzern.

Hitzkirch — Frau Prof. Ackermann-Lang.
Luthern — J. Suppiger.
Luzern — Kap.-Kloster Wesemlin.
St. Urban — J. Schwyzer, Portier.
Weggis — Frau S. Naef.

11. Kanton Neuenburg.

La Brévine — M^{me} J. Matthey, part.
La Chaux-de-Fonds — Pythoud-Jacot.
Neuchâtel — Observatorium.
Les Ponts — A. Erb, horloger.

12. Kanton Schaffhausen.

Lohn — Götz, Lehrer.
Schaffhausen — G. Meyer, Lehrer.
Schleitheim — G. Neck, Reallehrer.
Stein a. Rh. — H. Bächtold, Reallehrer.
Unter-Hallau — H. Huber, Lehrer.
Wilchingen — E. Hablützel, Lehrer.

13. Kanton Schwyz.

Rickenbach — Prof. O. Flüeler, Sem.-Lehrer.

14. Kanton Tessin.

Bellinzona — A. Lienhard, Postbeamter.
M^{te} Brè — G. Buzzzi, Direktor.

Crana-Torricella — P. Petrochi, guardiano.
St. Gotthard — Fr. Lombardi.
Locarno — G. Mariani, Professor.
Lugano — G. Malatesta, Professor.

15. Kanton Thurgau.

Aadorf — Joh. Nater, Lehrer.
Bischofszell — H. Fischer, Sek.-Lehrer.
Diessenhofen — Jakob Indlekofer.
Frauenfeld — Dr. S. Dannacher, Professor.
Haidenhaus — J. Stamm.
Kreuzlingen — J. Brauchli, Sem.-Lehrer.
Steckborn — Paul Hartmann.

16. Kanton Unterwalden.

Engelberg — N. Kaeser, Pater.
Sarnen — P. Ch. Durrer, Professor.

17. Kanton Uri.

Altdorf — Fr. Heinrika Nager.
Andermatt — Fortverwaltung.
Isental — Ferdinand Aschwanden.

18. Kanton Waadt.

Montreux — C. Lecoultré, pharmacien.
Gingins — L. Bigneus, forestier.
Lausanne — D. Valet, concierge.
Leysin — Max Bouët.
Montcherand — M. Moreillon, insp. forest.
Payerne — P. Baume.

19. Kanton Wallis.

Sierre — Luc Port, curé.
Sion — Couvent des capucins.
Visp — W. Burlet, pharmacien.

20. Kanton Zürich.

Hinwil — Ed. Benz, a. Lehrer.
Horgen — E. Gattiker.
Metmenstetten — Hess, Lehrer.
Opfikon — H. Schlittler, Lehrer.
Rheinau — Pfllegeanstalt.
Uster — H. Weber-Schellenberg, Fabrikant.
Wil (Rafz) — R. Angst, Friedensrichter.
Zollikon — J. Fausch, Verwalter.
Zürich — Meteorolog. Zentralanstalt.

21. Kanton Zug.

Walchwil — F. Bachmann.

[illegible]

sondern als diejenige Summe, welche erhalten wird, indem man für jeden Hagelschlag die betroffenen Gemeinden in Rechnung zieht, so dass also eine und dieselbe Gemeinde mehrmals darin figurieren kann.

Beschreibung der Gewitter und Hagelschläge.

In der tabellarischen Zusammenstellung sind die an jedem nennenswerten Gewittertage aufgetretenen elektrischen Erscheinungen in gedrängter Kürze angeführt. Für die Zeitangaben wurde die Stundenzählung 0—24 (M.-E. Z.) angewendet, also 6^h = 6 Uhr morgens, 18^h = 6 Uhr abends und, wie bisher, 0^h = Mitternacht, 12^h = Mittag. Die in Kolonne 6 notierte Fortpflanzungsgeschwindigkeit des Gewitters (Weg in Kilometern pro Stunde) ergibt sich nicht, wie man vielleicht anzunehmen versucht ist, aus den Kolonnen 3 und 5, sondern aus den Zeitangaben der Isobronten in der kartographischen Darstellung. Kolonne 7 stellt durch die bekannten Symbole ($\mathbb{K}$ = Gewitter, $\mathbb{L}$ = Blitz, $\mathbb{T}$ = Donner, $\mathbb{X}$ = Schnee, $\bullet$ = Regen, $\triangle$ = Graupeln oder Riesel, nur vereinzelte oder sehr kleine Hagelkörner, $\blacktriangle$ = Hagel, $\mathbb{S}$ = Sturm), die Art der Niederschläge und eventuell durch beigefügten Index deren Intensität dar.

Für jeden Gewittertag ist die allgemeine Wetterlage des Kontinents in knapper Form vor der Beschreibung des Hauptgewitters angegeben.

Der geographischen Angabe der Zugrichtung folgen die direkt vom Gewitter betroffenen Beobachtungsstationen.

In der gleichen Kolonne wurden weitere elektrische Erscheinungen wie Blitz, Donner, Wetterleuchten, sowie Hagel- und Graupelnfälle aufgenommen. Ferner figurieren unter dieser Rubrik diejenigen Tage, von denen die Gewittermeldungen in zu geringer Zahl einliefen, oder zu ungenau ausfielen, um eine kartographische Darstellung zu erlauben. In solchen Fällen wurden die Kolonnen 2—6 offen gelassen. Dem Texte beigefügte, mit dem Masszeichen m versehene Zahlen geben, sofern nichts weiteres bemerkt ist, den Tagesbetrag des Niederschlags auf der betreffenden Station an. (Leider wird nur von wenigen Beobachtern der während eines Gewitters gefallene Niederschlag gemessen.) Direkt nach dem Gewitter gemessene Niederschläge wurden mit ($\mathbb{K} \bullet \dots$) bezeichnet.

Spezielle Notizen einzelner Berichtersteller über die Witterungsvorgänge wurden dieses Jahr aus praktischen Gründen mit in die tabellarische Zusammenstellung der Gewitter aufgenommen. Am Schlusse sind die bekannt gewordenen Blitzschläge angeführt.

Die folgenden, der Kürze halber meistens ohne nähere Bezeichnung gebliebenen Stationsnamen, können folgendermassen präzisiert werden: Corcelles (sur Chavornay), Davos (Davos-Platz), Gingins (Gingins s. Chéserey, Nyon), Gsteig (b. Saanen), Kilchberg (Baselland), Küsnacht (Kt. Zürich), Küsnacht (Kt. Schwyz), Langnau (Kt. Bern), Münster (Kt. Luzern), Muri (Aargau), Nisellas (Nisellas-Alvaschein b. Tiefen-Castel), Oberkirch (Hof Oberkirch b. Kaltbrunn), Pfäffikon (Kt. Zürich), Rickenbach (b. Schwyz), Rossenges (s. Moudon), St^a Maria (im Münstertal, Graubünden), Schatzalp (bei Davos-Platz), Splügen (Dorf), Varen (Varen-Leuk), Waldhalde (Elektrizitätswerk an der Sihl bei Schönenberg, Kt. Zürich), Wald (Zürcher Sanatorium auf Hittenberg b. Wald), Wasen (im Emmental), Wil-R. (Wil-Rafz, Kt. Zürich), Zollikon (Schweiz. Anstalt für Epileptische b. Zollikon, Kt. Zürich).

Erklärung zu den Tafeln.

Die am Schlusse beigefügten 24 Kärtchen (1:3000000), welche eine durch J. Hess ausgeführte Reduktion der vom Bearbeiter im Massstab von 1:1000000 gezeichneten Originalbilder sind, sollen einige Tage mit charakteristischen Gewittergebilden zur Anschauung bringen. Die Bezeichnung der einzelnen Gewitterzüge mit a, b, c etc. ist chronologisch und entspricht den in der tabellarischen Uebersicht angegebenen Buchstaben (vergl. Rubrik 2). Die Kurven (Isobronten) verbinden die Stationen mit gleichzeitigem Gewittereintritt im Zenith des Beobachters. Gestrichelte Isobronten sind inter-, resp. extrapoliert; sie sollen andeuten, dass sie nicht mit genügender Sicherheit gezogen werden konnten. Geschlossene oder schraffierte Isobronten bedeuten Zonen, in denen gleichzeitig an mehreren Orten lokale Gewitter, sogenannte Wärmegewitter und andere Gewittererscheinungen — ohne deutliche Bewegung — stattgefunden haben. Die Pfeile geben die Richtung der Gewitter an. Am Rande der Kurven angebrachte Zahlen bezeichnen die Zeit (M.-E. Z.) in Stunden und Viertelstunden von 0—24 Uhr (5₁ = 5¹/₄ Uhr morgens, 17₃ = 5³/₄ Uhr nachmittags, 0₂ = 12¹/₂ Uhr nachts etc.). Einzelne Punkte bezeichnen die Lage lokaler Gewitter oder solcher, von denen die Angabe der Zugrichtung fehlt. Die an Stelle genauer Zeitangaben oft verwendeten Buchstaben bedeuten: a = vormittags, p = nachmittags und n = nachts.

Tabellarische Zusammenstellung der Gewitterzüge und Hagelschläge.

La trombe du 12 Juin 1926, dans le Jura neuchâtelois et bernois.

Le soir du 12 Juin 1926 un cyclone orageux d'une violence extraordinaire traversa notre pays du Jura neuchâtelois jusqu'à la région st-galloise du Rhin. Il fut accompagné d'une trombe qui ravagea le Jura neuchâtelois et bernois détruisant tout sur son passage dans une bande large de 300 à 1000 m et longue d'une vingtaine de km. Les dévastations commencèrent sur la colline de Pouillierel au nord-ouest de La Chaux-de-Fonds et s'étendirent jusqu'à la région des Breuleux. Des forêts entières furent détruites, des maisons complètement démolies.

Ce phénomène présente une très grande analogie avec le cyclone du 19 août 1890, voir dans le bulletin de la Société Vaudoise des Sciences Naturelles, Vol. XXVII, No. 103, 1891:

«Notice sur le cyclone du 19 août 1890 en France et à travers la Vallée de Joux.» par Louis Gauthier.

Nous publions ici in extenso une description du phénomène due à la plume de Monsieur le Pasteur Herzog, de la Ferrière (Jura bernois), observateur météorologique et membre de la société astronomique de France.

La tempête du 12 Juin 1926.

Dans l'après-midi du 12 Juin 1926 un orage d'une intensité particulière a fait sentir son action dans tout le Jura, sur une grande partie du Plateau-Suisse et ne s'est éteint que sur la branche st-galloise du Rhin. Cet orage a été marqué dans le Jura neuchâtelois et bernois par des destructions de maisons et de forêts qui rendent son étude tout particulièrement intéressante.

Observant les orages dans le Jura depuis plus de 20 ans, j'ai été chargé par le Bureau Fédéral de Météorologie de condenser tous des renseignements recueillis pour l'étude du phénomène et le présent rapport est le résultat de plusieurs courses dans la région sinistrée, de nombreux interrogatoires de témoins et de patientes investigations. Les journaux de la Suisse Romande ont aussi fourni leur appoint dans la collection des renseignements figurant ici.

Que s'est-il passé le 12 Juin?

Pour le comprendre, il faut d'abord examiner la carte du temps établie par le Bureau Fédéral.

Dès le 9 Juin on voit apparaître dans les parages de l'Irlande une forte dépression atmosphérique. Le 11, le résumé général des observations parle déjà de la *ligne de grain* qui avance: «Le minimum sur le nord-ouest de l'Europe n'a pas changé de position mais il est devenu encore plus profond (755 mm). Une ligne de grain, partant de lui se manifeste momentanément à travers la France jusqu'au nord de l'Espagne et vraisemblablement atteindra aussi notre pays jusqu'à demain.»

Dans le résumé du 12 (qui nous est arrivé le 13 seulement et après coup) la ligne de grain est annoncée pour le soir même en Suisse.

Cette prédiction s'est réalisée à la lettre et un régime tempétueux s'est fait sentir ce jour-là à travers toute la France et jusqu'à l'extrême frontière orientale de notre petit pays.

Nous devons nous borner à dire ici ce qui concerne spécialement notre région. Nous n'ignorons pas qu'elle est conditionnée météorologiquement par les grandes fluctuations cycloniques et anticycloniques de la région boréale et que nous dépendons des courants généraux qui soufflent sur l'Europe entière, mais nous devons nous souvenir que de l'Océan Atlantique aux Alpes en direction W-E. le Jura est la première chaîne de montagnes dépassant 1000 m que ces courants rencontrent, et que le choc du vent contre une chaîne de montagne produit souvent des effets remarquables, ce qui fut le cas pour la journée qui nous s'occupe.

Nous admettons donc que le 12 Juin une ligne de grain sévissait sur toute la France et nous menaçait de son fouet pour la soirée. Nous savons par les renseignements journalistiques que l'ouragan a causé des dégâts ailleurs que chez nous, que le vent a atteint en plusieurs endroits de Bordeaux à Lyon, à Besançon, Morteau, Les Brenets etc. une intensité de 5, 5,5 et même 6 de la semi-échelle de Beaufort. Nous ne nous en occuperons pas dans ce rapport et nous bornerons à dire ce qui, à notre avis, s'est passé chez nous.

Première partie: Sur territoire neuchâtelois.

1. Les prodromes.

Une première constatation à faire c'est le brusque changement de *température* qui s'est produit dans la nuit du 11 au 12 Juin. Notre station a noté les chiffres suivants pour la journée du 11:

matin 4,0 midi 10,0 soir 8,0.

Le 12 à 7 $\frac{1}{2}$ h la température atteint déjà 12,5 pour s'élever à 20,0 à 8 h. En même temps nous notons que le vent est nul (tourniquet de la girouette immobile) et que l'air est lourd, oppressant. Les nuages sont épais et s'amoncellent en gros cumulus aux contours floconneux laissant entre eux néanmoins quelques coins de ciel bleu.

A midi il se forme à l'extrême horizon ouest une ligne sombre d'un noir d'encre et tout en dinant, je fais cette remarque à ma famille: «Le ciel ne me plaît pas, la journée ne se passera pas sans qu'il y ait de la casse.»

En effet, à mesure que les heures avancent, la ligne sombre s'accroît de plus en plus et les nuages du zénith deviennent de plus en plus denses. Cependant, à midi, le vent est encore nul ou souffle que par petites bouffées indécises tôt éteintes.

A 15 h 46 je note le premier coup de tonnerre entendu en direction WSW. Depuis mon observatoire j'ai un excellent point de repère en direction WSW. C'est la colline dénudée de Pouillierel à 8 kilomètres à vol d'oiseau. C'est donc derrière Pouillierel que je remarque le premier éclair visible mais tout l'horizon ouest jusqu'au NNW (direction Charquemont sur le Plateau franc-comtois) est également noir, orageux, et le tonnerre gronde sur toute la ligne du Doubs. En général les orages qui viennent de ce côté suivent le cours du Doubs par Clerval et aboutissent à la trouée de Belfort ou aux Vosges. J'espère donc un moment que cette fois encore nous serons épargnés mais à 16 h 37 l'orage prend subitement une direction perpendiculaire à la frontière suisse et vient franchement de l'ouest.

Voici une description de M. Ed. Kaiser de la Chaux-de-Fonds publiée par «L'Impartial».

«Le plateau franc-comtois est recouvert d'une panne de nuages noirs superposés comme des couches géologiques. La partie inférieure est couleur d'encre. Elle colle au terrain. Dans le sens

vertical, elle se présente comme une muraille gigantesque le long de laquelle éclatent des éclairs nombreux. Ce sont des décharges internubaires, engendrées par la différence de potentiel des strates nuageuses, qui sont de densités différentes et frottent l'une contre l'autre.»

Qu'est ce qui a provoqué *ce changement de direction*?

Il est possible comme l'a écrit un article de journal que notre région se trouvait alors sous un régime spécial de basse pression provoquant un appel d'air considérable. M. H. Bühler écrit en effet:

«Le baromètre baisse à la colonne météorologique (de La Chaux-de-Fonds). A minuit il accusait une pression de 677 mm, à midi 674 mm, peu avant la tempête 670 mm. C'est qu'aussi bien l'air se raréfie sur la vallée de La Chaux-de-Fonds.»

Bien que je n'aie pas constaté à La Ferrière une chute aussi considérable de la colonne barométrique, je suis d'accord avec la conclusion de M. Bühler: l'appel d'air est formidable à ce moment-là. La ligne de grain partie de l'Irlande nous arrive, et nous arrive en direction ouest-est, *incontestablement*.

bien des jours plus tard comme immédiatement après son passage par la position des objets (toitures, arbres, murs) qu'elle a touchés.

Le point de départ peut être repéré très exactement légèrement en dessous du sommet de Pouillerel. En arrière de cette éminence il n'y a pas de dégâts qu'on puisse lui attribuer. Il est vrai que l'on a signalé des dégâts à Morteau, aux Brenets... A mon avis, ils sont indépendants de la tornade que nous étudions. Nous admettons plutôt qu'ils ont été le résultat d'autres trombes plus restreintes dont les causes sont d'ailleurs les mêmes que celles exposées ci-dessus en tenant compte de la disposition géographique locale des lieux sinistrés.

Sur place, à Pouillerel, en plein accord avec les observateurs chaux-de-fonnières, et avec les témoins immédiats, je constate lors de mes prospections que les arbres du bord sud de la tornade sont renversés ou brisés vers le centre de celle-ci (spire rentrante) tandis que les arbres du bord nord sont souvent (pas toujours) renversés en sens contraire de la direction générale. Ce que j'appelle la *spire sortante* n'est pas constamment réabsorbée par l'appel d'air qui suit immédiatement la tornade et ses molécules font l'effet de projectiles.

Le mouvement tourbillonnaire est donc incontestable et ceci dès le début. L'appel d'air se fait d'ailleurs sentir bien au delà des limites strictes de la tornade et un peu partout, à droite et à gauche, il y a des arbres brisés et déracinés, des tuiles emportées. La ville de La Chaux-de-Fonds a assez souffert de ce chef, et au Parc du Petit Château on a compté plusieurs arbres abattus.

Formée à Pouillerel, la tornade affecte la forme d'un champignon. Son sommet se trouve dans les nuages, sa pointe rase le sol. Suivant les témoignages recueillis, elle avance dans une position inclinée et arrache tout sur son passage. Il est vrai qu'elle paraît être plus ou moins élastique et rebondit parfois comme une balle de foot-ball: ce qui explique que certains objets restent intacts (ou à peu près) au milieu des destructions environnantes.

La tornade descend le flanc nord-est de la colline de Pouillerel après avoir ravagé le côté sud-est et une partie du côté nord. Elle descend au *Haut des Combes* (1156), elle démolit les maisons des *Joux-Dessus*, elle écrase les fermes et les maisons du quartier du *Chalet* (1094 m) où on mentionne particulièrement les fermes Leuba, la Belle-Maison, le restaurant de Jérusalem etc. Aux *Bulles* les fermes Geiser et Jacot sont anéanties. Aux *Rochettes* (1019 m) les toits sont enlevés ou déplacés. Tout le long du *Vallanvron* des arbres sont abattus. Enfin elle se perd dans la Combe de La Ferrière le long d'un couloir rocheux appartenant à la propriété Rohrbach. A cet endroit son diamètre n'est plus que de 20 m sur le plateau, 3 à 4 m au plus au fond de la Combe (850 m).

Sur ce premier tronçon de sa route, soit exactement 8 kilomètres, relevons quelques particularités.

Je l'ai déjà mentionné, les arbres de la forêt de Pouillerel et de la Sombaille qui lui fait immédiatement suite sont tous fauchés et jetés pêle mêle dans un fouillis indescriptible. Si la direction de chute peut-être relevée sur les bords de la tornade, cela devient impossible dans la région centrale. Monsieur Jules Ducommun de La Chaux-de-Fonds a bien voulu me remettre une photographie d'un sapin qui s'est trouvé au centre même du tourbillon. On constate que les branches sont enroulées autour du tronc en plusieurs sens différents tandis que la cime est arrachée par le mouvement vertical et transportée on ne sait où. Grâce à obligeance de M. Ducommun, nous joignons cette photographie à notre rapport. Ce transport de cimes arrachées aux arbres restés enracinés a été fréquent. Un propriétaire me dit qu'il a retrouvé le sommet caractéristique d'un sapin lui appartenant à 350 m du point de départ.

Dans cette région passablement peuplée les dégâts sont particulièrement graves aux maisons dont 25 sont découvertes ou renversées tandis qu'une quinzaine d'autres subissent des dommages plus ou moins graves.

Il serait trop long de rapporter ici tous les épisodes que les journaux ont rapportés. Bornons-nous à quelques faits caractéristiques.

Une mort. Un enfant, le jeune Fernand Gerber, 8 ans, revenait des Joux-Derrières à la Chaux-de-Fonds en compagnie de sa mère. Soulevé par la tornade il a été roulé plusieurs fois sur le sol, repris en l'air, finalement projeté violemment contre un mur. Un bras et une jambe brisés, le ventre ouvert, le crâne fracturé, le pauvre enfant a expiré à 3h du matin après 10 heures d'agonie. Ce fut la seule victime humaine du sinistre. Mme. Gerber-Nussbaum, sa mère, a aussi été roulée à terre et assez sérieusement blessée. Ces détails nous sont fournis par Mme. Gerber-Oppliger, la grand-mère de la petite victime.

Blessés. Six autres blessés plus ou moins gravement atteints mais sans que leur vie soit en danger ont été conduits à l'Hôpital de la ville.

Bétail. Dans la ferme Louis Geiser à la croisée de la Route cantonale avec le chemin des Bulles, 6 pièces de bétail ont été tuées dans l'écurie qui s'est effondrée sur elles. M. Geiser lui-même enseveli jusqu'aux épaules dans les décombres a été l'un des grands blessés mais sa vie a été épargnée. Quant à sa maison, incendiée par la foudre en 1921 puis rebâtie, elle était toute neuve et n'en a pas moins été écrasée par le courant d'air.

La maison Julien Jacot qui lui fait suite a été plus mal arrangée encore. C'est à peine si les murs sont restés debout. Un char a été projeté à travers toute la maison et est venu s'abîmer devant celle-ci dans le jardin en démolissant un pan de mur. On a eu beaucoup de peine à retrouver les 4 roues qui avaient été brisées et éparpillées.

Renseignements personnels de M. Julien Jacot, aux Bulles.

Au moment où l'ouragan se déchaîna, je me trouvais dans un petit bois à quelques dizaines de mètres de ma propriété. Subitement, avec une rapidité extraordinaire, l'horizon s'obscurcit. Un gros nuage noir s'approcha de terre. Il roula avec une vitesse formidable le long du sol. Il semblait que toutes les maisons étaient la proie d'un violent incendie tandis que les forêts paraissaient se soulever et s'élever dans les airs. On aurait dit qu'elles étaient attirées par un puissant aimant. Un bruit formidable régnait dans la nature, bruit qui n'avait rien de commun avec celui de l'orage ni avec celui du tonnerre. C'était un bruit assourdissant, continu. Les arbres semblaient tourner comme une vrille. On les voyait se dégager du sol, tourner un moment en l'air, puis retomber mais aucun craquement n'était perçu. Un phénomène très curieux se passa. Il me parut que l'endroit où je me trouvais, dont quelques arbres furent épargnés, s'abaissait et qu'autour de moi tout le reste de la nature filait dans le ciel. Il est impossible de dire combien de temps le phénomène dura. Peut-être deux minutes, peut-être quelques secondes.

Aux Rochettes plusieurs maisons ont eu leur toit emporté. Dans l'une d'elles le toit qui a résisté a néanmoins été déplacé sur les murs et la propriétaire me fait remarquer que les chevrons sont déjetés de 30 centimètres au moins vers le NE.

A partir de la Monsenière (altitude 1000 m) dans l'axe de la trombe, les dégâts sont limités aux arbres et ceci dans une zone qui s'effile en forme de cône pointu.

Nous avons recueilli le témoignage particulièrement intéressant du propriétaire des Escaliers (altitude 970 m) à l'extrémité du Plateau du Vallanvron. La tornade a passé sur son pré avant de s'engouffrer dans le couloir rocheux dont nous avons parlé. Au moment de son passage, sa famille et lui se trouvaient dans la cuisine dont la fenêtre regarde le SW, exactement direction de Pouillerel. Tout à coup l'obscurité s'est faite presque complète. D'épais brouillards chassés par un vent effréné enveloppaient la maison. En même temps la grêle faisait sauter les 6 carreaux de la fenêtre et des grêlons gros comme des oeufs étaient projetés comme des balles à travers tout le local. M. Frutschy et les

siens se sont sauvés en toute hâte à l'autre bout de la maison dans l'écurie. Quand ils en sont sortis, l'ouragan passé, ils ont vu la forêt de leur voisin Rohrbach à 125 m de chez eux fauchée sur une largeur de 20 à 30 m.

M. Frutschy me dit que chez lui il n'y a pas un arbre endommagé et que les dégâts se bornent à des vitres et à des tuiles cassées par la grêle.

Il est donc évident pour moi que la tornade avait bien réellement la forme en entonnoir ou en champignon que plusieurs témoins lui ont attribuée. La portion agissante et dévastatrice de grand diamètre se tenait à une altitude absolue de 1000 à 1300 mètres. En dessous de cette altitude, il ne s'agissait plus que d'une pointe effilée, tout aussi active (la forêt est rasée ou décapitée) mais d'un diamètre très restreint. Au fond de la Combe de La Ferrière, deux ou trois arbres seulement sont couchés en travers du lit à sec du ruisseau La Ronde. Sur la rive droite de celle-ci: plus rien.

4. Quelques incidents et impressions.

Nous transcrivons ici quelques renseignements supplémentaires publiés dans les journaux de la région.

«Un fermier nous a raconté qu'entendant le vent hurler en tempête, il se précipite pour fermer la porte de la grange. Mais au même moment la porte d'entrée de la maison s'ouvrait. Un formidable courant d'air s'établit et le toit

s'envola littéralement dans les airs. Le fermier lui-même fut protégé par ce fait curieux qu'il vint s'accrocher par sa blouse au montant de la porte de la maison qui très solidement construite ne s'effondra pas.

«Un automobiliste chaux-de-fonnier qui passait près de la Belle-Maison au moment où le coup de vent se déclancha, reçut sur sa voiture une partie du toit de l'édifice. La machine est en piteux état. Le conducteur a reçu des blessures superficielles.

«Une automobiliste qui revenait de Maïche (France) vit sa voiture danser sur la route, elle bondissait sur le sol et faisait d'effrayantes cabrioles. Le moteur tournant à pleins gaz parvenait à faire du 10 km à l'heure, tellement la violence du vent était grande. Après avoir vu le spectacle qui s'offrait à ses yeux aux environs de La Chaux-de-Fonds, la même automobiliste refusa de retourner sur les lieux. Elle déclara que c'était une véritable épouvante.

«Un autre fermier raconte: Le ciel devint mauvais. On s'empressa de faire rentrer le bétail de la pâture. Une fois le bétail à l'écurie on alla goûter. Or on avait à peine commencé lorsque l'ouragan se déclancha d'un coup. C'était un bruit d'enfer. Tout dégringola dans la maison. Nous nous précipitions dehors. C'est fait: Le toit est loin.»

Arrêtons ici ces citations. Nous en retrouverons d'autres relatives à la partie bernoise à laquelle nous arrivons maintenant.

Seconde partie: Sur territoire bernois.

5. Le passage de la tornade devant La Ferrière.

Nous l'avons dit plus haut: au moment critique de l'arrivée de l'orage, j'ai dû cesser d'observer pendant un instant afin de sauver les poussins. Quand je me suis remis aux observations, voici ce que j'ai vu.

D'abord en revenant du jardin, nous avons eu beaucoup de peine à arriver jusqu'à la porte d'entrée de la maison tant le vent était fort. Puis passant devant mon baromètre, je remarque un soubresaut de l'aiguille de 2 mm de chute. Enfin m'approchant d'une fenêtre qui donne sur le Vallanvron, je vois un *grand nuage gris, effilé par le bas*, qui sort rapidement de la Combe et se précipite vers la Chaux d'Abel où il semble s'écraser sur le sol près des maisons Stauffer & Schmidt (Rochat et Alverne). En même temps un bruit semblable à celui du roulement d'un train sur un viaduc de fer nous fait comprendre qu'une grosse grêle n'est pas loin. Toute la coulisse de la Chaux d'Abel s'emplit de vapeurs gris-noirâtres au sein desquelles les éclairs se produisent.

Il est 17 h 10 m (chronomètre) au moment où la tornade sort de la Combe. Quelques minutes plus tard un appel au téléphone de M. Antoine Jungen à la Basse Ferrière m'invite à y descendre (1 kilomètre) pour constater les dégâts causés dans ce quartier par la grêle.

Au village même, autour de la station, la grêle a été rare. Quelques grêlons isolés, *gros comme des noix* sont tombés ici ou là. Dans le jardin, un tel m'avait frôlé l'épaule gauche.

Quand j'arrive à la Basse Ferrière, accompagné du chef de gare M. Robert Stauffer, nous trouvons dès la croisée de la vieille route descendant de la Forge avec la Route Cantonale des *grêlons gros comme des oeufs de poule ou de carnard*, quelques uns aplatis comme des *disques* de 5 cm de diamètre et de 1½ à 2 cm d'épaisseur. Il en a été pesé de 60, 70 et 75 grammes. Tous ces gros grêlons sont évidemment formés par la congélation simultanée de grains de grosseur habituelle (noisettes). Les uns sont opaques, d'autres sont de vrais morceaux de glace transparente.

On nous affirme en avoir ramassé de plus gros encore: *comme le poing et même davantage*. Nous reviendrons plus loin sur cette question.

Dans le groupe des maisons de la Basse Ferrière cette grosse grêle a brisé bon nombre de tuiles (3 à 4 cents chez M. Jungen). La grosse maison Bonnot n'a plus aucune vitre entière du côté nord-ouest et dans les deux maisons suivantes ne sont intactes que les fenêtres qui étaient protégées par des volets.

Revenons pour le moment à la tornade.

Deux observateurs de la Chaux d'Abel, Mme Wäfler et son fils, qui étaient derrière leur maison située près de la cote 1069 sur le versant non atteint de la coulisse, ont pu suivre la tornade depuis son départ à Pouillerel jusqu'au bout du Vallanvron. Là, le tourbillon en forme d'entonnoir leur a paru *sauter* par dessus la Combe, puis retoucher terre vis-à-vis de chez eux, d'abord par la pointe, puis en semblant s'écraser sur le sol.

Cette observation confirme absolument ce que j'avais vu moi-même depuis la Ferrière avec cette différence que je voyais la trombe par derrière, tandis que les Wäfler la voyaient de profil. C'est à l'endroit désigné par eux que les dégâts recommencent.

Du côté nord, j'ai recueilli le témoignage fort instructif de M. H. Prêtre, administrateur postal du bureau des Bois. De ses fenêtres donnant vers le sud, il a vu le gros nuage noir tourbillonnant «comme une roue de moulin» sur la forêt à 2 kilomètres vis-à-vis de lui. Au sein de ce nuage s'élevaient perpendiculairement des masses noires, prises d'abord pour des toits de maisons puis qu'il a reconnues pour des sapins. Ceux-ci montaient en l'air à une assez grande hauteur tout en suivant le mouvement du tourbillon de droite à gauche, puis retombaient sur le sol. M. Prêtre n'a pas compris tout de suite ce qui se passait. Il en a reçu l'explication par l'arrivée aux Bois de M. Jean Jobin du Crêt Brûlé venu en courant aux Bois chercher du secours. Celui-ci pleurait en racontant ce qu'il avait vu en traversant la région sinistrée dans laquelle il avait à faire au moment de la catastrophe. C'est à ce moment que les pompiers des Bois ont été mobilisés pour venir au sauvetage des maisons sinistrées dont nous parlerons plus loin.

Voici maintenant les déductions que nous pouvons tirer des observations faites:

La *trombe* a rencontré dans la Combe, le courant d'air chaud descendant qui suivait le couloir à angles brisés remontant de Biaufonds sur le Doubs jusqu'à La Ferrière. Elle a été en quelque sorte soulevée par ce courant d'air, ce qui explique que la rive droite de la Combe est épargnée. Une fois au-dessus du plateau de la Large Journée-Cerneux-la-Pluie, elle retombe et dès que le plateau atteint 1000 m d'altitude, exactement 1009 m vers la halte du Régional Saignelégier-Chaux-de-Fonds (où il y a déjà un sapin abattu) la partie agissante reprend contact avec le sol et les dégâts recommencent. La direction est d'ailleurs toujours rigoureusement la même soit SW-NE. Seule la Combe et le courant d'air qui s'y produit peuvent expliquer cette solution de continuité de 1600 m dans les effets de la tornade.

En outre, si l'on prend la peine de poser une règle plate sur la série des cartes au 25 millième depuis Pouillerel au Vallanvron avec prolongement vers les Chaux d'Abel, on remarque que l'axe du *tourbillon* est déjeté de 250 m vers le sud. Ce *crochet* n'est explicable que par l'influence du courant de la Combe qui doit avoir été très violent.

Tout de suite après le passage de la tornade, tous les habitants de La Ferrière ont été surpris de voir passer dans le ciel ce qu'on a pris d'abord pour un vol d'oiseaux. En y faisant mieux attention, on a remarqué que les objets qui passaient rapidement au dessus de nos têtes à une hauteur de 40 à 50 mètres étaient des feuilles arrachées aux arbres, des rameaux entiers, des clavins (petites tuiles en bois mince qu'on place sur les toits sous les vraies tuiles), des journaux, des morceaux de toile, etc. Toute cette marchandise provenait évidemment des destructions accomplies un moment auparavant aux Bulles et que le vent tenait en suspension par la violence même de sa course.

6. Le long des Chaux d'Abel.

Retouchant terre à la halte du Régional, la tornade se manifeste de nouveau, suivant nos constatations par le mouvement tourbillonnaire droite-gauche. Elle passe au nord des maisons Baume, Bärtschy, vielle poste. Les forêts en dessus pâtissent: Chez M. Aurèle Bärtschy, il y a déjà plus de 300 sapins abattus. La première habitation sérieusement endommagée est celle de M. Paul Maurer à la Frontière entre les Communes de la Ferrière de Sonvilier. Son toit est en partie soulevé et la buanderie derrière la maison renversée ainsi qu'un gros pommier. Le pâturage boisé tout proche est rasé complètement sur une largeur de 200 mètres. J'y note un grand sapin qui présente absolument le même aspect que celui photographié à la Sombaille par M. Jules Ducommun (voir première partie).

Depuis là, toujours en direction NE la tornade passe derrière le Restaurant du Raisin & la Fruitière, au lieu dit «Chez les Brandt» à la cote 1044. Là, deux incidents se produisent.

Un jeune homme qui cassait des pierres au bord de la route cantonale veut s'enfuir dans la maison toute voisine. Il n'en a pas le temps. A peine debout, il est projeté à plat ventre sur le sol et il doit y rester jusqu'à la fin de la tourmente.

Sur le chemin qui traverse le pâturage un char venant des Bois et amenant un porc (Propriétaire M. Frésard) est renversé. Le porc se sauve on ne sait où. Il a été retrouvé plus tard. Le cheval, affolé par les gros grêlons qui le mitraillent, s'emballe et va se déchirer la tête contre les branches d'un sapin que le vent renverse sur lui. Un oeil arraché, la joue déchirée, il n'a pu être dégagé que tard dans la soirée et il a fallu l'abattre. Quant au domestique qui conduisait le char, il a dû s'accroupir sur le sol, la tête entre les genoux, les bras par dessus pour la protéger contre la grêle qui lui a occasionné quelques meurtrissures..

A la cote 1036, il se produit un élargissement de la *trombe*: je serais même disposé à admettre qu'elle se scinde en deux.

Une branche secondaire tourne vers la droite, effleure la maison James Isler et sa remise, emporte le toit de la maison

David Geiser et renverse complètement le bas de la forêt de la Grande Coronel, puis cette branche diminue d'intensité sur le pâturage de la route cantonale et vient rejoindre la branche principale par une petite dépression vis-à-vis de la cote 1045. Dans ce ravin tous les grands arbres sont abattus, les petits restent debout. La branche principale, dans l'axe direct se rue tout d'abord sur les 2 maisons Christian Schnegg qu'elle démolit presque complètement, puis elle atteint le quartier dit «Vers la Chapelle». Là les maisons s'échelonnent comme suit en remontant de la route cantonale vers le NW.

1) La petite Coronel, habitée par le coiffeur Rech, entièrement démolie, les murs à 1½ m du sol. Mme Rech, blessée à la joue par une brique qui l'effleure est sauvée par miracle bien que le plafond de la chambre se soit effondré. 20 poules sont écrasées dans leur poulailler. Le mobilier est en majeure partie fracassé.

2) Ecole des anabaptistes: toit emporté, toutes les vitres brisées, l'eau de la pluie pénètre partout.

3) La ferme Pierre Geiser: toit retourné sens dessus dessous, murs lézardés. Citons:

«Un fils Geiser qui se trouvait au pâturage, a été atteint à la tête par une branche d'arbre. Il s'en tire avec une déchirure du cuir chevelu. Des membres de cette même famille, l'une des plus éprouvées, qui se trouvaient dehors ont dû à cause de la violence du vent se coucher sur le sol pour ne pas être renversés, mais le vent était tel qu'ils furent roulés sur une distance de plusieurs dizaines de mètres.

4) La Chapelle: toit en partie emporté, vitres cassées. Un magnifique poirier en espalier est brisé à raz du sol.

5) Ferme Fritz Sauser: toit emporté aux ¾.

Les annexes, remises, bûchers subissent le même sort et un râcher est anéanti.

La forêt descendant vers la *tourbière* et l'étang de la Chaux d'Abel est rasée: il ne reste pas un arbre debout.

Au nord de l'étang, le mouvement spiraliforme est de nouveau caractéristique.

Ici la tornade avec sa branche secondaire de droite atteint un diamètre maximum de près de 1500 mètres.

Voici encore une impression que publie l'Impartial:

«J'étais à 20 mètres de ma maison, raconte un fermier de cette région, lorsque la *trombe* fondit sur nous. Je la vis déboucher du bois comme un énorme *tourbillon* noir. A son sommet, haut dans l'air, une masse sombre faisait comme un bruit de moteur. Elle retomba tout à coup à 200 mètres de moi; c'était un sapin enlevé par le *tourbillon*. A ce moment le vent devint si fort qu'il me poussa presque à terre. Je m'enfuis dans ma maison qui n'eut, Dieu merci! qu'un coin de toit démolé.» Le cataclysme passa si vite que personne n'eut le temps de se rendre compte de ce qui arrivait.

7. Cerneux-Veusil — Les Fonges.

Sur la *tourbière*, entre la Chaux d'Abel et le Cerneux-Veusil, rien ne s'opposait à la marche de l'ouragan. La tornade aspire à droite le petit bois qui dominait la Route cantonale, cote 1052. Le bois est rasé et les arbres déracinés ou brisés recouvrent en partie la route. A gauche, vis-à-vis, aucune des maisons du Cerneux-Veusil-Dessous n'échappe à ses effets. Plusieurs sont totalement décoiffées. C'est le cas du Restaurant du Sapin au bord de la route, cote 1027. Dès ce moment la route semble être exactement l'axe de la rafale. La tornade semble animée d'un véritable mouvement de sautellement. «Vers chez les Boillet» la petite maison du cantonnier au bord de la route perd seulement le faite du toit tandis que la forêt à l'entour est rasée. Des bouquets d'arbres entiers échappent à l'action du *tourbillon* tandis que tout à côté il y a chaos et destruction.

Dans la forêt du Cerneux-Veusil des groupes d'arbres sont renversés au milieu d'étendues où il n'y a pas le moindre mal.

Le paroxysme de l'intensité paraît s'être produit au *Bois des Fonges*, des deux côtés de la route cantonale. Là tous les sapins sauf 7 sont couchés en un fouillis inextricable. Le hameau des Fonges lui-même et les quelques maisons «Derrière Chalery» ont énormément souffert. Ainsi nous notons un toit qui a été descendu tout d'une pièce à côté de la maison.

Dans cette région, des poulains au pâturage ont été tués sous les arbres renversés. L'un d'eux a eu les reins brisés en pleine fuite. On l'a retrouvé, le tronc d'un sapin par dessus lui, deux jambes d'un côté, deux de l'autre.

Sur la tourbière, un voiturier M. Albert Beuret des Ravières (Je parlerai plus loin de son frère) passait avec son char conduisant du pain. Il raconte:

Brusquement je me suis senti soulevé de terre. J'étais suspendu en l'air au-dessus de mon attelage. Mes chevaux et ma voiture, eux aussi volaient. La preuve en est que l'on peut encore suivre dans le pâturage détrempé la trace de leur course endiablée: les sabots sont marqués, après chaque bond, tous les 8 ou 10 mètres. Et ma voiture, elle a perdu ses roues, ses essieux dans ses sauts désordonnés: il n'en reste qu'un amas informe de bois déchiqueté et de fers tordus. Quant à moi, je suis retombé, pas trop violemment, sur le côté, et il me semble avoir fait un voyage dans l'autre monde.»

Les pains de 6 livres aspirés par le cyclone ont été éparpillés: on ne les a plus revus.

Remarquons qu'au dessus des prés Gogniat, le mouvement «spire sortante» est de nouveau bien visible au-dessus de la route du Peu-Chapatte aux Vacheries. Là, plusieurs arbres sont fauchés du NE au SW, et ils se trouvaient pourtant passablement en dehors de la zone sinistrée, proprement dite. La tornade a d'ailleurs désormais une tendance à s'élargir, ou mieux à se sectionner en plusieurs tourbillons distincts, comme nous l'avons déjà vu à la Grande Coronel.

Mentionnons encore ici ce fait remarqué encore ailleurs que la tornade a démolie plusieurs murs de pâturages en pierres sèches. Par exemple il a été remarqué un bloc de pierre que deux hommes forts ont peine à soulever et qui a été projeté à plus de 10 mètres de son point de départ. Ce détail indique la force de la pression exercée par la tornade.

8. Le dernier secteur; Vacheries — Brenleux-Chaux.

Après le Bois des Fonges, devant la tornade, s'ouvrait un grand espace découvert bordé au Nord par la colline au flanc de laquelle est bâti le hameau des *Vacheries*, au sud par une *petite arête boisée* (cote 1036), premier contrefort du Mont Soleil. Puis vient le village des *Brenleux* en une longue pente, et derrière celui-ci, l'immense pâturage plat que traverse la route de Tramelan.

Dans ce secteur l'axe principal de la trombe longe exactement le sommet de l'arête où presque tous les sapins sont fauchés. Il touche ensuite le bas du village des Brenleux dont la plupart des maisons en dessous de la ligne du régional électrique T. B. N. sont endommagées, surtout la maison Alfred Jeandupeux, à quelques mètres en dessous de la gare du régional et qui finira complètement, 3 jours après (15 juin) par un incendie provoqué dans les décombres par un court circuit.

Enfin la trombe se perd dans le grand pâturage, cote 999 m Au-delà, vers le NE, dans la forêt du Biclet, il y a peut-être encore par place un ou deux sapins déracinés, mais la base de la tornade ne touche plus le sol.

A côté de cet axe principal, un tourbillon secondaire frappe le hameau des Vacheries où plusieurs maisons, quatre surtout, sont endommagées. Ce tourbillon se perd sans avoir atteint le quartier de l'Eglise des Brenleux, ou plutôt, il rebondit pour retomber sur La Chaux où les quelques sapins qui entourent la gare du régional sont fauchés. L'un d'eux tombant sur la ligne électrique

a mis celle-ci hors d'usage jusqu'à réparation. Deux cents mètres plus loin, la tornade enlève le toit de la maison Antoine Frésard et la démolit. Ce dernier exploit du phénomène est caractéristique.

De l'autre côté du chemin (5 m) qui monte du pâturage une maison voisine n'a que quelques tuiles enlevées. Son propriétaire, qui me renseigne, était à la fenêtre. Tout à coup le ciel est devenu tout noir, comme à 9 h du soir. Alors j'ai vu le toit de la maison Frésard se soulever en l'air tout d'une pièce à une hauteur de 2 ou 3 m au dessus des murs, puis se rompre et retomber partie sur le chemin devant ma maison, partie dans la maison Frésard entraînant de grands pans de murs. La poussière était si épaisse qu'on l'a prise pour de la fumée; on a crié au feu! et les pompiers sont accourus. Ils ont ainsi pu aider au sauvetage.

Ce voisin ajoute que le bruit du vent ressemblait à celui que feraient «mille moteurs d'avions évoluant à la fois».

La maison ainsi détruite est probablement une des plus grandes fermes du Jura; carrée, elle a au moins 40 mètres de côté. Il n'en reste qu'un monceau de ruines.

Un bébé de trois mois se trouvant dans son berceau a été renversé sur le sol par une poutre tombée du plafond et miraculeusement protégé par une porte de l'étage supérieur descendue de façon à former une niche chargée d'un bon mètre de décombres des murs effondrés. Il a fallu user de la hache pour ouvrir un passage par où un jeune garçon a pu enfiler son bras, attraper le bébé par un pied et le sortir de sa fâcheuse et dangereuse position. Les recherches ont été facilitées par les cris de l'enfant qui pleurait sous les ruines. (Détails fournis par Mme Frésard, la grand-mère.)

Après avoir enlevé encore un toit de bardeaux au haut du village de La Chaux la trombe a décapité 157 sapins du pâturage communal, arbres dont les cimes ont été retrouvées dans la tourbière en dessous puis elle a entièrement quitté le sol, et plus loin, Chaux de Tramelan, La Joux, Sornetan etc. on ne parle plus d'elle. L'orage ne se manifeste plus que par un vent de 5,5 ou de 5 de l'échelle de Beaufort.

Revenons au Bois des Fonges.

Depuis là un tourbillon secondaire remonte par le sud, met à mal quelques toits aux Ravières, au Pré Garçon, à l'Engosse, abat en partie la forêt qui domine le petit contour de la Route de Tramelan en dessous de la cote 1044 et se perd.

Aux Ravières, M. Jules Beuret, le frère de celui qui a eu son char si mal arrangé sur la tourbière, me montre les débris de ce véhicule dont en effet il n'y a plus deux pièces qui tiennent ensemble: puis il me décrit le passage de la tornade.

Depuis la porte de sa grange, il a vu le nuage tourbillonnant comme «une grande roue tournant avec une rapidité vertigineuse, projetant derrière elle des arbres et des débris de toutes sortes. La couleur de ce nuage était d'un gris-noir sinistre. Il s'en échappait continuellement de petits tourbillons blancs qui filaient comme des projectiles et qui tournoyaient là où ils paraissaient s'arrêter. On est sûr de trouver en ces endroits 2 ou 3 arbres abattus au milieu des autres restés intacts. On n'entendait pas de craquement lors de la rupture des arbres mais un grondement continu comme celui d'une puissante rivière bondissant sur des rochers. Le tout a passé rapidement et a duré au plus une minute».

La force de ces petits tourbillons tertiaires est encore suffisante pour fracasser des arbres: J'en mentionne un vers l'Engosse qui est fractionné en trois segments encore rattachés l'un à l'autre par quelques fibres, l'arbre s'étant accroché à ses voisins. Il est d'ailleurs débranché et la cime est arrachée.

J'ai porté aussi mes investigations sur le côté nord de la tornade et j'ai interrogé des habitants du *Peu-Clande* et du *Peu-Chapatte*. Dans ces deux hameaux la trombe n'a pas passé mais bien en dessous d'eux dans la coulisse plusieurs fois nommée déjà.

Au Peu-Claude, quelques dégâts par la grêle et un arbre renversé sous le hameau, dans le pâturage. Les témoins interrogés n'ont rien de spécial à dire sinon qu'il faisait «un rude temps».

Au Peu-Chapatte, il a été impossible de rien voir. A leur altitude de 1129, les gens se sont trouvés en plein nuage orageux.

«Des brouillards terribles sont arrivés directement de l'ouest, on ne voyait plus à dix mètres devant soi», dit l'un. Un autre: «De la porte de ma maison, je ne voyais pas ma remise, là, vis-à-vis, de l'autre côté du chemin. En même temps la foudre éclatait tout à coup et c'était tout près. En outre la grosse grêle tombait fort et on croyait que c'était la fin du monde.»

Après l'éclaircie, ils ont pu voir des arbres renversés à la lisière de la forêt juste en-dessous du village. Le bruit du vent dominait tout et on n'entendait que son hurlement prolongé. L'heure exacte de l'arrivée de la tornade aux Breuleux et à la Chaux n'a pu être déterminée. Les uns disent «vers 17 h et quart», d'autres «un peu avant 6 heures du soir». Il n'y a rien de précis et quand on sait combien peu nos paysans tiennent à avoir l'heure exacte, on n'est pas surpris de cette imprécision. En tous cas, et ici tous les témoins sont d'accord, la tornade marchait avec une rapidité extraordinaire: «comme un train express» m'a-t-on dit quelque part. Ma première supputation de 25 m à la seconde était certainement insuffisante. En se basant sur l'heure de 7 h 15 aux Breuleux j'ai admis ensuite 45 m à la seconde, ce qui est peut-être beaucoup, bien que les effets aient été proportionnels à la rapidité du courant. Le chiffre le plus juste serait probablement 40 m à la seconde, ce qui est déjà le souffle des grandes tempêtes.

Une remarque intéressante me paraît être celle faite d'un bout à l'autre du passage. *On n'a entendu aucun autre bruit que celui du vent.* Le craquement de la rupture des arbres n'a été perçu nulle part. Ainsi M. Pierre Geiser à La Chaux d'Abel me disait le même soir:

«Je voyais la forêt se coucher autour de moi comme les épis de blés quand le vent les incline, mais ça ne faisait pas de bruit.

Comment expliquer ce phénomène?

Grâce à la pression énorme régnant au sein de la trombe, ou au contraire au vide d'air intérieur provoqué par l'aspiration, la tornade formait comme un milieu clos au sein duquel les vibrations acoustiques s'évanouissaient sans pouvoir s'échapper au dehors. Le seul bruit était par conséquent celui des molécules d'air elles-mêmes agitées en mouvement tourbillonnaire, bruit comparé suivant les uns à une rivière se brisant sur les rochers, suivant les autres à un bruit de moteurs ou à un hurlement prolongé.

J'ai noté ailleurs déjà que les coups de foudre étaient assez nombreux, un par minute au moins, se produisant surtout entre nuages, mais qu'on ne les entendait guère. Il y a deux raisons pour cela:

D'abord la faible hauteur des nuages orageux (300 m). La crépitation d'un éclair court ne pouvait être que faible. Puis le fracas du courant d'air lui-même était assez fort pour annihiler les autres bruits, même celui de la foudre.

Et je serais même disposé à admettre que le tout produisait un vacarme tel que les ramifications nerveuses de l'oreille humaine n'arrivaient plus à l'enregistrer.

9. La grêle.

L'orage venant de l'ouest amenait avec lui une large colonne de grêle. Nous l'avons déjà mentionnée à plusieurs reprises. J'ai constaté que cette colonne a exercé ses effets tout de long du flanc nord de la tornade. Celle-ci a emporté avec elle le nuage

à grêle et c'est à peine si au sud de son passage il est tombé quelques grêlons épars.

En revanche, au nord, depuis le Doubs jusqu'à la zone sinistrée, elle fut cruelle et dévastatrice. Citons plutôt quelques observations des journaux:

«Dans les gorges du Doubs, déjà tragiques par un temps calme, l'ouragan prit une allure titanesque. On se fut cru dans la forge de Vulcain, où les coups de tonnerre roulaient comme le bruit des marteaux sur l'enclume et où les grêlons atteignant la grosseur d'un poing d'homme tombaient en nuées de projectiles meurtriers. A terre, sur les rampes, ce ne sont que feuilles arrachées, et branches coupées net. Le joli parc des Sonneurs a été littéralement dévalisé par la grêle, tandis que le restaurant de la Maison-Monsieur et l'école ont des carreaux et des tuiles cassées.»

Au moment où l'ouragan sévissait avec violence, à La Ferrière, une société de La Chaux-de-Fonds, qui rentrait de promenade en auto-car, eut deux de ses membres blessés à la tête par de gros grêlons. Les deux victimes ont été soignées à La Ferrière.»

D'autres cas du même genre, meurtrissures, contusions, m'ont été aussi signalés aux Bulles, à la Chaux d'Abel, etc.

La région la plus gravement atteinte est celle de la Combe de La Ferrière, La Planche, La Large-Journée, Les Murs. Aux Bois même, il y a eu un grand nombre de vitres cassées comme d'ailleurs nous l'avons vu, à la Basse Ferrière.

Sur les pâturages des Murs, les gentianes (*Gentiana lutea*) sont absolument hâchées; il n'y a plus une seule feuille entière. L'herbe des prés et des pâturages est perdue. Un paysan des Murs me disait: «Nos foins sont faits.» Il en est de même des fermiers de la Cernie des Aiges au fond de la Combe et de la Planche.

10. Le post-orage.

Après le passage de la tornade et des 2 orages combinés qui l'ont provoquée, le ciel reste menaçant. Comme je l'ai dit, je suis descendu à ce moment à la Basse Ferrière sur l'invitation téléphonique de M. Jungen. Je m'y trouvais encore qu'éclatait le second orage dont les roulements se sont fait entendre de 17 h 50 à 19 h.

Son altitude était supérieure et cette fois, les coups de foudre bruyants frappaient terre. Nous en avons une preuve dans l'aventure suivante du chef de la Police de La Chaux-de-Fonds, le lieutenant Liechti.

Avisé qu'une dame Guyot avait été blessée aux Joux-Dessus par la chute d'un sapin, le chef de police était parti immédiatement au secours de cette personne avec son side-car. Il rapporte ce fait inouï. Alors qu'il se trouvait près de la ferme Jeanmaire, la foudre tombe sur une clôture à quelques centimètres de la machine arrêtée. Il se forma sur la route comme *une boule de feu* qui monta sur la roue du véhicule. Une sorte d'explosion s'en suivit et M. Liechti fut violemment projeté dans la champ voisin. Il n'eut heureusement aucun mal mais ressentit une forte commotion en même temps qu'une émotion bien compréhensible. La marche de cet orage était WSW-ENE et il a été accompagné d'une pluie abondante et d'une petite grêle pendant 5 minutes avec des grains gros comme des pois et des noisettes, cette fois assez denses à la station, mais qui n'ont pas causé de dégâts.

L'eau tombée en tout au cours de cette après-midi a fourni au pluviomètre 19,3 mm.

Le temps est resté pluvieux et maussade plusieurs jours encore. Il ne s'est vraiment remis au beau que le 20 juin.

11. Conclusions.

Dans la tempête du 12 juin 1926, nos observations personnelles, celles des témoins interrogés, ainsi que nos investigations sur le terrain à pied, en vélo, en auto, etc., les photographies

exposées, et tous les renseignements et commentaires fournis par les journaux nous permettent de dire :

Ce jour fatal, il y a eu :

- 1) Un orage (ligne de grain) accompagné de grêle venant de l'ouest par dessus le Plateau français de la Franche-Comté.
- 2) Un second orage simultané venant du sud et comme le premier à une altitude moyenne de 1300 m seulement.
- 3) La formation d'une tornade à Pouillerel provoquée par la rencontre de deux courants à angle droit dans une zone de basse pression atmosphérique.
- 4) La progression de la tornade en ligne moyenne des deux courants primitifs, soit SW—NE, sur une longueur de 40 km environ avec destruction de forêts et d'habitations sur 25 km au moins.

NB. En ce qui concerne le Jura Bernois, le président de la Commission d'estimation des dégâts m'a dit que leurs expertises avaient porté sur 206 immeubles plus ou moins touchés par la tornade ou par la grêle. Dans le Jura Neuchâtelais, 40 maisons ont été endommagées par la tornade.

- 5) L'averse de grosse grêle de 17 h 10 à 17 h 15.
- 6) Le post-orage de 17 h 50 à 19 h avec pluie, petite grêle et coups de foudre frappant terre.

J. L. Herzog.

Nous complétons ce rapport par des citations toutes empruntées au journal chaux-de-fonnier bien connu «L'Impartial».

«Peu après 17 h, on remarquait qu'un violent orage se donnait du côté de France; à 17 h 20 un énorme nuage, à l'ouest du Chapeau-Rablé était déchiré par le vent de plus en plus violent. Ce spectacle était à la fois curieux, grandiose et terrifiant. De ce nuage étaient arrachées avec furie des mèches énormes de nuages qui partaient avec une vitesse inouïe dans la direction est, balayant l'horizon. Sur le versant de la Recorne les éclairs ne cessaient pas. Le vent était d'une violence inouïe. Les carreaux des fenêtres furent criblés de sable, jusqu'au troisième étage. A l'est dans la direction de Biafond ou Goumois, un gros nuage noir, immobile, barrait l'assaut des vents déchaînés. A ce moment un coup de tonnerre bref se fit entendre. Alors une pluie, chassée à toute force tomba.

Voilà ce que j'ai aperçu. Je ne l'avais jamais vu de ma vie.»

La ville de La Chaux-de-Fonds même fût épargnée par la trombe, mais on y ressentit les effets de l'orage et de l'ouragan. Citons quelques observations: «Une espèce de nuage noir déroba la vue de la grande poste à trente mètres. C'était un opaque tourbillon de poussière tel qu'on n'en a jamais vu en notre ville.»

A La Chaux-de-Fonds la cloche d'alarme du Temple National battit le tocsin, mais «bien que les cloches sonnassent à toute volée, la violence du vent était telle que dans plusieurs quartiers de la ville on ne percevait aucun son. Des patrouilles d'officiers de pompiers se rendirent dans ces endroits et alarmèrent la population par des coups de trompette.»

Les forêts furent cruellement maltraitées.

«La plume se révèle impuissante à décrire les ravages des éléments déchaînés. Qu'on aille à Pouillerel, à la Sombaille, aux Bulles ou au Vallanvron, c'est un spectacle de désolation qui s'offre aux yeux de la foule accourue. Sur l'horizon assombré encore des dernières nuées, la forêt mutilée se détache. Sapins fracassés, les uns à quelques mètres du sommet, d'autres au milieu de leur tronc robuste, d'autres enfin à un mètre du sol, ou même couchés sur le flanc après avoir soulevé de leurs racines un bloc de terre et de rocher pouvant peser plusieurs quintaux.

C'est comme si l'on avait tiré à mitraille pendant des jours et des jours sur cette vieille amie qu'est la forêt et où les Chaux-de-Fonniers aiment tant à se rendre, les soirs d'été ou les dimanches de beau temps, pour jouir de l'air pur et frais de la montagne.

Le spectacle de nos forêts sur le versant de Pouillerel est absolument navrant. Toute l'étendue d'arbres située du sommet de Pouillerel jusqu'à l'endroit dénommé les Joux-Dessus est complètement rasée. La tempête a ensuite porté ses ravages sur le petit bois de l'Orphelinat des garçons qui présente actuellement l'aspect d'un véritable cimetière. La forêt de la Sombaille, le petit bois à l'entrée des Bulles ont également souffert de façon tragique. Mais où l'élément destructeur s'est déchaîné avec une rage inouïe, c'est dans la région allant depuis le Cerneux-Veuil jusqu'aux Breuleux. Cinq kilomètres de forêt située sur les bords de la route présentent l'aspect d'un champ de bataille, ravagé par les obus, haché par la mitraille et c'est à peine si un ou deux arbres sont encore debout. Tous les sapins sont couchés, lamentablement, sur le sol.»

La puissance de la trombe était inouïe comme le prouve le fait suivant :

«A La Chaux-d'Abel, nous avons vu un arbre qui avait été fauché à peu près à un mètre du sol et que nous avons retrouvé à 150 mètres au moins de sa base. Ce géant des forêts avait été balayé comme un fétu de paille, et pourtant son tronc mesurait 80 centimètres de diamètre. Au même endroit, deux sapins accolés se sont renversés et leurs racines, pleines de terre et de bloc de pierres forment une masse haute comme une maison. Spectacle inouï et formidable.»

La citation suivante donnera une idée des ravages subis par les maisons :

«Un même spectacle de désolation attendait les premiers sauveteurs à la Sombaille, où se dressaient autrefois des fermes prospères, bien fournies de bétail, avec un beau mobilier et un matériel agricole complet et moderne. Poutres, tuiles, cheminées, avaient volé en même temps que les chevrons solides à plusieurs mètres des murs eux-mêmes démolis. Malgré le niveau peu élevé du toit des fermes, construites spécialement pour supporter les fortes bourrasques de neige, toute la toiture avait été balayée et rasée, montrant l'intérieur de la maison au ciel ouvert qui déversait encore ses cataractes.

A la ferme Taillard, qui se trouve à gauche du chemin des Joux-Derrières, l'ouragan n'a laissé que quatre murs. Un robuste platane qui servait d'ombrage à cette grosse ferme, a été déraciné. Plus loin, les deux fermes Schafroth et Leuba sont également anéanties. Encore et toujours des toits que la bourrasque a littéralement soulevés, arrachés et réduits en miettes, les transportant à plusieurs mètres de distance, tantôt détruisant en même temps les murs, tantôt se bornant à recouvrir de débris les étables. Un char de purin qui se trouvait là fut soulevé de terre et transporté à 15 mètres de distance, puis déposé brutalement les quatre roues en l'air au milieu du champ. Le vent semble s'être engouffré sous les toits pour mieux les plaquer ensuite sur le sol. Il a renversé les plus solides fermes comme des châteaux de cartes. On retrouve des débris à plus de 500 mètres de la ferme. Une forte barre de fer qui courait le long d'un mur a été pliée à l'équerre. C'est à grand-peine que de ces décombres on put tirer ce qui restait du mobilier. Devant la première des fermes, spectacle navrant, se tient une pauvre vieille, pleurant, qui ne veut pas quitter les ruines du foyer détruit et que les pompiers emmènent avec des paroles émues de consolation. C'est dans une de ces fermes qu'un enfant de sept ans, fut blessé mortellement.»

Et encore :

«Les maisons de séjour Ducommun ont partiellement souffert, tandis que le grand bâtiment situé à proximité (la Belle-Maison) a subi le poids d'une complète calamité. Tout le toit et la parti.

supérieure de l'édifice sont détruits ou gisent au milieu des prés. Un mur de grosse maçonnerie s'est allongé au milieu du champ et les briques sont là, en carrés, très régulièrement alignées, comme si d'une baguette magique, ou d'un coup d'épaula formidable, on avait fait basculer le mur sur l'herbe fraîche. Un gros poulailler en maçonnerie également et dans lequel se trouvaient de nombreuses couvées, a été pour ainsi dire pulvérisé. On venait en outre de faire les jardins. Ajoutons qu'en cet endroit le concierge de la maison, M. Jules Perret, donnait à manger à ses poules lorsque éclata la tornade. M. Perret fut emporté par le vent et projeté à une très grande distance. On le retrouva dans le champ voisin, assez grièvement blessé.»

«Citons encore le cas curieux de ce paysan que le début extrêmement violent déjà du cyclone attira sur son seuil. Il vit ses vaches accourir du pâturage, se précipiter en se bousculant vers l'étable à l'approche du péril. La première allait y pénétrer quand la tourmente redoublant, la maison s'écroula. Elles durent à quel-retard d'être sauvées.

Deux femmes, ensevelies sous les décombres, sont parvenues à ramper entre les poutres et à se frayer un chemin sous les ruines. Un bloc de pierre de quelque 200 kilos est tombé aux pieds d'un enfant et de sa mère. Ils ont été tous deux coincés entre le piano et le mur la chambre et n'ont pas eu une égratignure. Plusieurs chevaux surpris par la chute des sapins ont été tués en plein pâturage. Maintes personnes occupées dans la forêt ne sont pas encore remises de leur terreur; elles couraient au hasard, affolées par le hurlement de la tempête et le craquement des arbres et ne comprennent pas comment elles ont pu sortir de la géhenne.»

«Des promeneurs ont été projetés à terre. Un particulier, qui traversait la forêt d'une ferme à une autre, a vu les arbres s'abattre autour de lui. Coincé entre deux plantes, il a dû attendre un certain temps que les pompiers viennent le tirer de sa périlleuse position.

A un autre endroit, une dizaine de personnes voyant dans le lointain s'abattre les forêts et la tornade s'approcher à toute vitesse, se massèrent derrière un rocher, collées les unes aux autres véritablement. Elles ne furent qu'éraflées au passage par les branches emportées dans la rafale.»

«Comme on voit, de tous les témoignages recueillis, il résulte que le cyclone s'est photographié comme un instantané dans la rétiné des témoins, qui n'ont pas eu le temps de réfléchir, pas eu le temps de faire des observations, pas eu le temps de se donner à eux-mêmes une explication. La tornade avait passé, enlevé les toits, détruit les maisons. Et ils restaient là, assommés sur place. Et maintenant, la pluie tombe. Elle donne le coup de grâce au termier qui assiste impuissant à l'inondation des fermes et à la pourriture du bois.»

«On signale la présence d'esprit d'une personne qui, se trouvant avec cinq compagnons dans une forêt voisinant les Breuleux, au moment où la tornade se déchaîna, prit une décision qui les sauva tous les six. Lorsqu'elle vit les arbres tourner et s'abattre, elle fit s'aligner ses cinq compagnons sous le premier sapin tombé. Toute la forêt s'écroula à côté d'eux, sans les atteindre.»

Et encore:

Nombreux furent les automobilistes qui virent les arbres s'abattre devant eux juste au moment où ils allaient franchir l'espace dangereux. Certains automobilistes durent faire 50 kilomètres pour rentrer à leur domicile, la route directe étant coupée. D'autres ne purent même pas rentrer avant qu'on eût scié les géants de la forêt couchés sur la route.»

Dans la région des Breuleux:

C'est ici que le cyclone a jeté bas les derniers sapins. Ils sont couchés par rangées, alignés les uns à côté des autres,

comme fauchés, ou bien, ils sont cassés à deux mètres de hauteur et leurs moignons déchiquetés et blancs se dressent dans la forêt comme des stèles, ou comme des pierres tombales.»

«Aux Vacheries des Breuleux, la maison de M. Alcide Donzé est complètement écroulée: un amas de poutre et de pierres. Une bonne dame pleure et regarde. «Tout est fichu, nous dit elle» et elle pense à son linge perdu, à ses meubles fracassés, à sa maison effondrée. «Ma petite fille, âgée de deux ans se tenait près du fourneau quand la poutraison s'est abattue à côté d'elle. C'est un miracle qu'elle n'ait pas été écrasée.»

«De chaque côté de la route qui va des Vacheries des Breuleux au Corneux-Veuil, une hécatombe d'arbres. Et c'est toujours par le même procédé spasmodique, semble-t-il, que la tornade a opéré. Des géants sont par terre à côté d'arbres frères restés debout. Dans un pan de pâturage resté intact, des troncs gisent, comme sciés et les branches coupées. Toute l'étendue qui va des Vacheries des Breuleux à la Chaux d'Abel offre du reste un tableau véritablement fantastique devant lequel les paroles sont impuissantes...»

Dommmages causés par la trombe du 12 Juin 1926.

Nous devons à l'obligeance du Département de l'Intérieur du Canton de Neuchâtel les chiffres suivants:

	Bâtiments mobil., cultur. et divers.	Forêts	Total
	Fr.	Fr.	Fr.
Le Locle	—	1,847.—	1,847.—
Les Brenets	15,258.—	3,334.—	18,592.—
Le Brévine	500.—	—	500.—
La Chaux-de-Fonds	452,790.—	97,040.—	549,830.—
	468,548.—	102,221.—	570,769.—

Nous signalons ici pour les lecteurs que ce côté de la question intéresserait le «Bulletin de l'Association des Etablissements cantonaux suisses d'assurance contre l'incendie». 5me année 1926. No. 2/3, page 154 à 163.

Nous nous permettons de répéter ici que contrairement à l'opinion exprimée par Monsieur Eugène Colomb dans le bulletin cité, le phénomène météorologique dont nous nous occupons est bien une trombe (voir les observations rapportées par Monsieur le Pasteur Herzog).

Nous extrayons du bulletin cité les chiffres suivants relatifs aux deux cantons de Neuchâtel et de Berne:

Dommmages particuliers.

Cantons:	Bâtiments		Mobiliér	Cultures	Total
	Nombre	dommage			
		Fr.	Fz.	Fr	Fr.
Neuchâtel	68	400,893.—	34,255.—	30,400.—	465,548.—
Berne	226	310,000.—	26,260.—	35,540.—	371,800.—
Total	294	710,893.—	60,515.—	65,940.—	837,348.—

Der Forstdirektion des Kantons Bern verdanken wir noch folgende Zahlen: „Es betrug die im Walde und den Wytweiden geworfenen Holzmassen:

Gemeinde Muriaux	6500 Fm. mit 22.— ha Waldfläche
„ Peuchapatte	4800 „ „ 19 50 „ „
„ Les Breuleux	21000 „ „ 60. „ „
„ La Chaux	200 „ „ 0.60 „ „
Privatwald, 32 Parzellen	3500 „ „ 14. — „ „
Total	36000 „ „ 116.10 „ „

Ausserdem betragen die anderweitigen, im Berner Jura konstatierten Schäden:

An Gebäuden und Mobiliar	Fr. 315.830.—
Kulturen	34.775.—
	<u>Fr. 350.605.—</u>

Zum bessern Verständnis fügen wir noch hinzu, dass man unter der der Abkürzung Fm. einen Kubikmeter Festholz zu verstehen hat.

Considérations météorologiques.

Il résulte clairement du rapport détaillé de Monsieur le Pasteur Herzog que les destructions de forêts et de maisons sont dues à une trombe, c'est à dire à un tourbillon de dimensions restreintes ayant la forme d'un cône renversé. Il résulte de nombreuses observations qu'au sein de la trombe la pression atmosphérique était beaucoup plus basse qu'ailleurs. Cette trombe était donc un tourbillon aspirant tous les objets se trouvant sur son passage. Il résulte également des observations rapportées par Monsieur Herzog que la trombe a été engendrée par la rencontre de deux violents courants d'air de directions différentes. Nous répétons ici que plusieurs personnes ont remarqué la forme en champignon ou en entonnoir de la trombe et ont vu son mouvement de rotation en sens inverse des aiguilles d'une montre.

Les courbes barométriques des stations météorologiques de la Suisse orientale montrent très nettement le passage de deux lignes de grain distinctes à environ une heure et demie d'intervalle. Le même phénomène apparaît aussi sur le barogramme de l'Observatoire de Neuchâtel mais l'intervalle est plus court, environ une demi-heure. Premier grain à 16 h 30 m exactement, deuxième à 17 h.

On retrouve le premier grain sur le barogramme de Lausanne peu après 16 h, mais le deuxième grain ne peut être décelé avec certitude sur cette courbe.

La carte du temps du 12 à 8 h du matin montre une dépression ayant son centre sur la côte NW de l'Irlande avec un centre secondaire sur la mer d'Irlande. Ce dernier a dû se former la veille au large SW des Iles Britanniques. Une ligne de grain s'étend à partir de ce centre dans la direction du sud à travers la France jusque sur le Golf de Gascogne. C'est cette ligne qui, comme l'annonce la prévision du matin, nous a atteint vers le soir et a été accompagnée du formidable orage et de la trombe que l'on connaît. Si l'on examine la carte de 14 h du même jour on est frappé par l'existence d'une zone de baisse sur le Jura et surtout par l'existence sur le plateau suisse d'un courant de bise bien caractérisé et directement opposé au vent de SSW régnant plus à l'ouest dans la vallée du Rhône, à Lyon par exemple. On ne voit pas comment concilier cette constatation avec l'observation faite dans le voisinage de La Chaux-de-Fonds de deux orages l'un venant de l'ouest et l'autre du sud. Il y a là un point à éclaircir. On est conduit à admettre qu'au cours de

l'après-midi la bise a été remplacée dans la région du Jura par un courant du sud, qui aurait été provoqué par la forte baisse du baromètre précédant l'arrivée de la ligne de grain.

Nous publions ici un certain nombre de courbes barométriques de divers observatoires suisses et français.

Comme il ne nous est pas possible de faire une étude détaillée du phénomène nous sommes dans l'obligation de publier ces barogrammes en nous abstenant de tout commentaire.

Nous donnons dans le tableau suivant la hauteur du baromètre dans les stations suisses.

Hauteur du baromètre le 12 Juin 1926.

	Lectures originales		Pression réduite à zéro degré	
	13 ¹ / ₂	21 ¹ / ₂	13 ¹ / ₂	21 ¹ / ₂
Zürich	715.6	716.4	713.5	714.3

Lausanne . . .	—	—	707.6	708.7
Château d'Oex .	673.7	675.6	672.0	673.9
Genève	—	—	720.4	721.0

Nous avons envers Monsieur le Pasteur J. L. Herzog de La Ferrière (Jura bernois) une dette particulière de reconnaissance. C'est lui qui a visité les lieux après le cataclysme et c'est à lui que nous devons la presque totalité des observations figurant dans notre rapport. Qu'ils nous soit permis de le remercier encore une fois ici.

Nous exprimons en outre nos remerciements à toutes les personnes qui nous ont fourni des documents ou des observations, à Monsieur le Professeur Raoul Gautier, Directeur honoraire de l'Observatoire de Genève, à Monsieur le Professeur P. L. Mercanton à Lausanne, à Monsieur le Dr. L. Arndt, Directeur de l'Observatoire de Neuchâtel, à Monsieur le Professeur Niethammer, Directeur du Bernoullianum à Bâle, à Monsieur le Professeur Ch. Borel à La Chaux-de-Fonds, à Monsieur le Général Delcambre, Directeur de l'Office national Météorologique à Paris, à Monsieur le Professeur Jean Mascart, Directeur de l'Observatoire de Lyon, à Monsieur A. Lebeuf, Directeur de l'Observatoire de Besançon, à Monsieur Roy, Directeur de la Station régionale de Physique et de Météorologie agricole de Dijon, pour les barogrammes qu'ils ont mis à notre disposition ou dont ils nous ont envoyé une copie. Nous remercions également la Direction du Service fédéral aérien à Dübendorf, ainsi que celle de l'aérodrome de Bâle qui ont bien voulu mettre à notre disposition des photographies de la région dévastée et nous autoriser à reproduire celles de notre choix, le Département de l'Intérieur du Canton de Neuchâtel et la Direction forestière du Canton de Berne qui ont eu l'obligeance de nous communiquer les résultats des expertises faites dans la zone dévastée. Nous remercions encore vivement Monsieur le Dr. J. Maurer, Directeur du Bureau Central Météorologique à Zurich, pour la sollicitude qu'il a apportée à notre travail.

Trajectoire de la Trombe du 12 juin 1926.

Relevé topographique par J. L. Herzog.
(La Ferrière.)

Barogrammes de stations françaises. 12. VI. 1926.

La pression est corrigée de la température
Les heures sont en temps moyen local

Barogrammes des stations météorologiques suisses. 12. VI. 1926.

Barogramme, Laboratoire de Physique Gymnase,
La Chaux-de-Fonds.

Maisons détruites

Cerneux-Veuil — Forêt dévastée.

Sapeurs-Pompiers débarrassant la route des Bulles près de La Chaux-de-Fonds
(le 13 Juin à 6 heures du matin).

Branches enroulées par la tornade, près de La Chaux-de-Fonds.

Forêt détruite.

La Chaux-de-Fonds. Chapelle.

Nr. 4.

Ergebnisse der Registrierungen des Sonnenscheinautographen im Jahr 1926

auf den Stationen:

Lugano, Genf*), Lausanne*), Montreux, Leysin, Montana s. Siders, Chaux-de-Fonds, Mont Soleil (ob St. Imier), Neuchâtel, Bern, Luzern*), Basel*), Wintersingen (Baselland), Hallau, Zürich, Plantahof (b. Landquart), Davos, Arosa, St. Moritz und Säntis.

*) Basel (Bernoullianum) besitzt seit Januar 1908 einen neuen Sonnenscheinautographen (Modell Negretti & Zambra); Genf desgleichen seit 15. Januar 1909, Lausanne seit Anfang Januar 1909 und Luzern seit Beginn 1910.

Die nachstehenden Tabellen geben einerseits für jeden Tag des Jahres eine synoptische Uebersicht der Sonnenscheindauer an den verschiedenen Stationen, anderseits die Monats- und Jahressummen der klimatischen Hauptgebiete unseres Landes.

Monats- und Jahressummen der Sonnenscheindauer in Stunden.

Nr. 5.

Jahresbericht 1926 des Erdbebendienstes

der Schweizerischen Meteorologischen Zentralanstalt.

Von Dr. Fritz Gassmann, Assistent des Erdbebendienstes.

1. Allgemeines.
2. Tabellarische Zusammenstellung der in der Schweiz verspürten und der an den Erdbebenstationen Zürich, Chur und Neuchâtel registrierten Erdbeben.
3. Statistische Bemerkungen und Besprechung einzelner Fälle.

1. Allgemeines.

Zu Beginn dieses Jahres wurde der Leiter des Erdbebendienstes, Prof. de Quervain, erneut von schwerer Krankheit heimgesucht, welche ihn über das ganze Jahr ans Haus fesselte. Trotzdem leitete er die Arbeiten des Erdbebendienstes durch Erledigung aller wichtigen Korrespondenzen und Abhaltung von regelmässigen Sitzungen mit dem Unterzeichneten, der die Arbeiten auszuführen hatte. Die tägliche Bedienung der Apparate besorgte mit gewohnter Zuverlässigkeit Herr Peter wie bis anhin.

Die laufenden Arbeiten nahmen dieses Jahr ungewöhnlich viel Zeit in Anspruch wegen der relativ grossen Anzahl von registrierten und von in der Schweiz gespürten Beben. Daneben wurde, ähnlich wie es voriges Jahr mit unsern 450 kg Mainka-Pendel geschehen war, auch die Eigenperiode des 80 kg Vertikalapparates Wiechert bedeutend vergrössert. Die dabei verwendeten rechnerischen Ueber-

legungen sind im Jahresbericht 1925 des Erdbebendienstes, Anhang Nr. 5: „Zur Umjustierung von Seismometern“, angegeben. Nach Vornahme einiger Aenderungen an den Dimensionen des Apparates konnte die Eigenperiode vom ursprünglichen Betrag von $3\frac{1}{2}$ Sekunden auf $7\frac{1}{2}$ Sekunden gebracht werden. Allerdings musste dabei die Luftdämpfung durch eine Oeldämpfung ersetzt werden, da ein an sich unscheinbares Zwischenglied der Luftdämpfung eine genügende Erhöhung der Eigenperiode des Apparates verhinderte. Mit dieser Umjustierung des Wiechert-Apparates ist nun erreicht, dass die Erdbebenwarte Zürich ausser dem für Nahebeben besonders leistungsfähigen 21-Tonnen-Universalseismographen de Quervain-Piccard einen Satz von drei Apparaten besitzt, welche sich vor allem zur Registrierung von Fernbeben eignen. Das internationale Sammel-Bulletin wurde in gewohnter Weise herausgegeben.

Die Instrumente in der Erdbebenwarte Zürich hatten am 23. September folgende Konstanten:

	Quervain-Piccard			Mainka		Wiechert
	N-S	E-W	Vert.	N-S	E-W	Vert.
Masse		20 600 kg		450 kg	450 kg	80 kg
Vergrößerung für schnelle Schwingungen	1510	1680	1700	114	112	111
Eigenperiode	3.3 ^s	3.0 ^s	1.3 ^s	9.6 ^s	9.7 ^s	3.6 ^s
Dämpfungsverhältnis	3.8	3.9	2.4	2.7	3.9	5.4
Reibungsausschlag	0.8 mm	0.7 mm	0.7 mm	2.2 mm	1.5 mm	0.3 mm
Registriereschwindigkeit	ca. 60 mm/Min.			ca. 30 mm/Min.		
Mittlerer Zeit-Interpolationsfehler	± 0.1 ^s	± 0.1 ^s	± 0.1 ^s	± 0.1 ^s	± 0.1 ^s	± 0.3 ^s
Art der Registrierung	mechanisch auf berusstes Papier.					

Das Berichtjahr stand ganz im Zeichen der Entstehung des neuen schweizerischen Stationsdreiecks Zürich-Chur-Neuchâtel. In Chur wurde dank der Energie und der praktischen Geschicklichkeit des Leiters der dortigen Station, Herrn Prof. Kreis, der neue Universalseismograph de Quervain-Piccard im September dieses Jahres provisorisch in Betrieb gesetzt mit folgenden ungefähren Konstanten: Masse 13 400 kg, Eigenperiode der Vertikal-Komponente 0.86 Sek., der Horizontal-Komponente (EW) ca. 3 Sek., Vergrößerung für rasche Schwingungen je ca. 1000 fach. Infolge Mangels an Platz im Keller des Kantonsschulgebäudes konnten bei diesem Apparat die T-Balken, an welchem das Pendel aufgehängt ist, nicht auf gesonderte Betonpfeiler gelegt, sondern mussten direkt in die Mauer des Kantonsschulgebäudes eingelassen werden. Diese Art der Installation liess starke Störungen durch den Schulbetrieb und durch den Wechsel in der Sonnenbestrahlung des Gebäudes befürchten. Die Erfahrung hat indessen gezeigt, dass die durch die Kantonsschüler verursachten Erdbeben erstens sofort als solche zu erkennen sind, und zweitens mit ungewöhnlich geringer Wahrscheinlichkeit eine wirkliche seismische Registrierung stören werden. Der Wechsel in der Bestrahlung des Gebäudes hat starke Verschiebungen des Nullpunktes der Horizontal-Komponenten zur Folge. Diesem begegnet man in Chur durch eine Kompensation. Sie besteht in einer automatischen Zurückführung der Masse in die normale Nullage durch eine Feder, deren Spannungsänderungen vom Registrierer gesteuert werden. Diese von Herrn Prof. Kreis selbst erdachte Kompensation hat sich bewährt und findet in gleicher Weise für die Kompensation der Vertikal-Komponente Verwendung. Der neue Churer Seismograph lieferte eine schöne Registrierung des Bebens vom 28. September aus dem Semmering-Wechselgebiet (Oesterreich) mit scharfen Phasen. (Siehe Tabelle II Nr. 78 dieses Jahresberichtes, sowie eine Reproduktion der Registrierung in unserm Sammel-Bulletin Nr. 65).

Im Gegensatz zu dieser Registrierung besitzt die entsprechende des Zürcher Seismographen keine ausgeprägten Einsätze. Die Herdentfernung von Zürich beträgt bei diesem Beben ca. 550 km, diejenige von Chur 90 km weniger. Diese Differenz scheint mir nicht genügend, um den grossen Unterschied im Aussehen der Diagramme von Chur und Zürich zu erklären, so dass man den Verdacht hat, der Molasseuntergrund, auf welchem die Erdbebenwarte Zürich steht,

verwische sozusagen noch im letzten Augenblicke vor Ankunft der Wellen die scharfen Unterschiede der Phasen. Dieser gleiche Verdacht stützt sich ferner auf eine mir von H. Jeffreys zugekommene Mitteilung über die Registrierungen vom 15. August eines Bebens in England (siehe Tabelle II Nr. 70 dieses Jahresberichtes), welche zu vergleichen er Gelegenheit hatte. Es fiel ihm nämlich auf, dass die Registrierungen des Seismographen de Quervain-Piccard in Zürich viel schwächer und mit undeutlicheren Phasen versehen waren, als die Registrierungen auf dem Apparat gleicher Konstruktion in Strasbourg. Auch hier kann ich mir diesen Unterschied nicht allein aus der prozentual geringfügigen Differenz der Herddistanzen allein erklären, sondern muss die verschiedene Beschaffenheit des Untergrundes dafür verantwortlich machen. Wenn einmal weiteres Vergleichsmaterial der Seismographen Zürich, Chur und Neuchâtel beieinander sein wird, kann zur hier angetönten sehr wichtigen Frage über den Einfluss der Beschaffenheit des Untergrundes auf die Registrierungen ein interessanter Beitrag geleistet werden. — Das Beben vom 15. Dezember aus dem Kanton Freiburg (siehe Tabelle I Nr. 42 und Tabelle II Nr. 93), gab erstmals Gelegenheit, vermittelt der miteinander kombinierten Angaben von Zürich und Chur ein zuverlässiges Epizentrum zu bestimmen, das mit dem durch makroseismische Angaben scharf definierten Epizentrum mit grosser Genauigkeit übereinstimmte. In diese erste Zeit der Zusammenarbeit der beiden grossen Seismographen von Chur und Zürich fällt auch die Erprobung eines vom Berichterstatter verfassten Telegrammschlüssels zum regelmässigen telegraphischen Austausch aller Registrierungen zwischen Zürich, Chur und Neuchâtel. Der internationale Schlüssel (siehe Jahresbericht 1920 des Erdbebedienstes) erwies sich als unzulänglich, da er keine Möglichkeit bietet, die Einsätze auf Zehntel-Sekunden genau zu übermitteln. Trotzdem nach dem neuen schweizerischen Code die Depeschen in der Regel nicht länger als nach dem internationalen werden, geben sie soviel Aufschluss, dass sich eine nachträgliche Meldung per Postkarte erübrigt und nur eine Zusendung der Original-Registrierungen wesentlich mehr zu bieten vermag.

Für den grossen Seismographen der Sternwarte Neuchâtel, der im Keller des Pavillons Hirsch aufgestellt wird, bot die Platzfrage erhebliche Schwierigkeiten, da der verfügbare Raum nach unten durch anstehenden Fels, nach

oben durch den Boden eines schönen Saales begrenzt war. Schliesslich wurde entschieden, den Boden zu durchbrechen und zudem die Pendelschläge im Vergleich zum Seismographen von Zürich um 1.5 m zu verkürzen. Diese Verkürzung wurde vorgeschlagen, nachdem am grossen Seismographen in Zürich Versuche mit der Astasierung einer Horizontalkomponente gut gelungen waren. Die dazu verwendete Einrichtung war im wesentlichen die gleiche wie

für die Astasierung der Vertikal-Komponente. So konnte vorgesehen werden, in Neuchâtel das Minus an Pendellänge durch Anbringung von Astasierungseinrichtungen für die Horizontal-Komponenten wettzumachen. Zur Einführung in den Erdbebendienst war Herr Dr. Odermatt, Adjunkt an der Sternwarte Neuchâtel, für zwei Wochen im Erdbebendienst der meteorologischen Zentralanstalt mit Erfolg tätig.

2. Tabellarische Zusammenstellung der in der Schweiz verspürten und der an den Erdbebenstationen Zürich, Chur und Neuchâtel registrierten Erdbeben.

Tabelle I enthält sämtliche zur Kenntnis des Erdbebendienstes gelangten Meldungen aus der Schweiz über wirkliche oder vermeintliche gespürte Erdbeben. Nur die von uns als wirklich seismisch erkannten oder vermuteten Fälle sind numeriert, die höchst zweifelhaften oder sicher nicht

seismischen überdies durch kleineren Druck gekennzeichnet. Tabelle II enthält die an einer der obgenannten Stationen registrierten Erdbeben aus einer Distanz von höchstens 1000 km von Zürich, Tabelle III die aus einer Distanz von über 1000 km von Zürich.

Tabelle I. In der Schweiz verspürte Erdbeben. 1926.

Z = Erdbebenwarte Zürich.

C = Erdbebenstation Chur.

N = Observatoire Neuchâtel.

24	Juni 28.	22. 47	Ibach (Schwyz)	II	—	1	—	Z	Ein leichter Erdstoss. S. a. Tab. II, Nr. 39.
25	„ 28.	23. 01	Kaiserstuhl (Breisgau). In einem grossen Teil der Schweiz gespürt, namentlich in der Nord- und Westschweiz (bis Grad V). Gegen Süden und Osten wird das makroseismische Schüttergebiet begrenzt durch positive Meldungen aus folgenden Ortschaften: Thal (bei Rheineck), Teufen, Betschwanden (Kt. Glarus), Locarno, Montana (Wallis), Sitten, Genf	V	—	255	14	Z,N	Die Leute wurden aus dem Schlaf geweckt durch 1—2 kräftige Stösse, die meist als horizontal verlaufend angegeben wurden. Hängende Bilder schlugen an die Wand, Geschirr und Fensterscheiben klirrten, im Gebälk war ein Krachen vernehmbar. Gegen die Grenzen des Schüttergebietes wurde das Erdbeben mehr als wellenförmige Bewegung empfunden. Siehe auch Tabelle II, Nr. 41.
26	„ 28.	23. 12	Langnau im Emmental	II	—	1	—	Z	„Zwei schwächere Stösse“. Nachstoss des Bebens Nr. 25 von Kaiserstuhl. Siehe auch Tab. II, Nr. 43.
	„ 28.	ca 23. 30	Obermeilen	—	—	1	—	—	„Wie Lastauto-Erschütterungen“.
	„ 28.	ca 23. 55	Mümliswil (Kt. Solothurn)	—	—	1	—	—	„Ein weniger heftiger Stoss“ (als um 23 ^h 01 ^m dieses Tages).
	„ 29.	ca 1. 05	Neuhausen	—	—	1	—	—	Rollen, Schwanken eines Lampenvolants.
27	„ 29.	ca 2. 15	Eptingen, Mümliswil	IV	11	3	—	—	Senkrechter Stoss.
28	„ 30.	5. 24	Zürich	II	—	2	—	Z	Wie Lastauto-Erschütterung. Siehe auch Tab. II, Nr. 46.
29	Juli 1.	3. 24	Lausanne	II	—	1	—	—	Zittern mit Rollen.
	„ 5.	13. 45	Hochsteig bei Lichtensteig	—	—	1	—	—	Wellenförmiges Schwanken, auf der Strasse stehend gespürt.
	„ 6.	ca 5. 10	Zürich-Enge	—	—	1	—	—	30 Sek. dauerndes Rollen, darob erwacht.
	„ 14.	ca 2. 14	Zofingen	—	—	1	—	—	Schwacher Stoss (nur von einer Person gespürt).
	„ 19.	ca 23. 45	Grenchen	—	—	1	—	—	Leichter Stoss (nur von einer Person gespürt).
30	„ 20.	0. 38	Grenchen	II	—	1	—	Z(p)	Leichter Stoss, gespürt von einer Person im 2. Stockwerk. S. auch Tab. II, Nr. 62.
31	„ 30.	14. 22	Jersey (Normannische Inseln), vereinzelt gespürt in Basel und bei Locle	II	—	2	—	Z,N	Ein Zittern. Siehe auch Tab. II, Nr. 70.
	Aug. 19.	ca 0. 29	Oberrieden	—	—	1	—	—	Leichter Erdstoss.
32	Aug. 19.	22. 59	Im Schams, Rheinwald, Domleschg, Oberhalbstein, Bergell, auf der Lenzerheide und in Vals	IV	48	11	10	Z	Stoss, Zittern, begleitet durch ein dumpfes donnerartiges Geräusch. Siehe auch Tab. II, Nr. 71.
	„ 25.	ca 11. 30	Zürich	—	—	1	—	—	Erdstoss.
33	„ 30.	ca 4. 52	Montana bei Siders	II	—	1	—	—	Durch ein leichtes Beben ist ein Beobachter geweckt worden. Ein Gegenstand im Zimmer kam in Schwingung.
34	„ 30.	12. 41	Griechenland, vereinzelt gespürt in Zürich und in Minusio (Locarno)	II	—	2	—	Z,N	Einige Sekunden dauerndes Zittern (Zürich), 4 Erdstösse (Minusio). Siehe auch Tab. III, 92.
	Sep. 10.	ca 23. 15	Neuhausen	—	—	1	—	—	Vertikaler Erdstoss mit Geräusch.
	„ 13.	ca 21. 00	Zürich	—	—	1	—	—	Wellenförmige Bewegung.
35	Sept. 13.	21. 03	Wildhaus, Schafboden und Thierwies am Säntis, Alt St. Johann	IV	7	3	7	Z	„Starker Vertikalstoss mit explosionsartigem, dumpfem Knall. Siehe auch Tab. II, Nr. 76.“
	„ 14.	ca 0. 57	Zürich	—	—	1	—	—	„Heftige Erschütterung“.
36	Okt. 1.	14. 58	Langwiesen (bei Schaffhausen)	II	—	1	—	Z	„Rumpeln im Estrich.“ S. auch Tab. II, Nr. 80.
37	„ 7.	ca 3. 30	Hettlingen (bei Winterthur)	V	—	1	—	—	Erdbeben mit Geräusch von rasch rollendem Lastauto, in zwei Häusern lösten sich Gipsstückchen v. den Decken.

87	" 10.	149	0.9	1	iP 12 ^h 57 ^m 36.4 ^s , iS 57 ^m 56.2 ^s . Herd vermutlich im Wallis.
88	" 18.	279	1.7	4	ePn 23 ^h 58 ^m 40.3 ^s , iS 59 ^m 19.2 ^s . Gespürt in Bagnone, Toscanischer Appennin.
89	" 21.	150	0.7	1	iP 8 ^h 19 ^m 14.3 ^s , eS 19 ^m 33.3 ^s . Herd im Wallis. Siehe auch Tab. I, Nr. 40.
90	" 29.	—	0.7	3	eP 22 ^h 13 ^m 12 ^s . Herd in Italien.
91	" 30.	63	8.1	3	iP 11 ^h 56 ^m 11.6 ^s , iS 56 ^m 20.1 ^s . Epizentrum am Sarnersee, identisch mit demjenigen von Nr. 33 dieser Tabelle. Siehe auch Tab. I, Nr. 41.
92	Dez. 3.	136	5	1	eP 7 ^h 50 ^m 51.2 ^s , iS 51 ^m 8.4 ^s . Herd nach Strasbourg in der Gegend von Remiremont, Vogesen.
93	" 15.	127	42	6	iP 14 ^h 59 ^m 06.4 ^s , iS 59 ^m 22.5 ^s . Azimut S 48° W. Chur: iP 59 ^m 15.6 ^s , iS 59 ^m 37.3 ^s , d = 172 km. Epizentrum nach diesen Angaben und übereinstimmend mit dem makroseismischen Epizentrum 46° 43' N, 7° 13' E v. Gr., Kanton Freiburg. Siehe auch Tab. I, Nr. 42.
94	" 15.	127	4.5	1	eP 15 ^h 29 ^m 53.0 ^s , iS 30 ^m 09.1 ^s . Nachstoss des Bebens Nr. 93 aus dem Kanton Freiburg.
95	" 16.	—	—	—	Zürich: Spuren. Chur: iP 21 ^h 59 ^m 34.8 ^s , iS 59 ^m 38.8 ^s , d = 20 km. Gespürt im Engadin. Siehe auch Tab. I, Nr. 43.
96	" 17.	1000	58	15	eP 7 ^h 33 ^m 48.8 ^s , eS 35 ^m 37 ^s . Chur: iP 33 ^m 24.4 ^s . Zerstörend in Nord-Albanien.
97	" 17.	1140	31	15	eP 12 ^h 41 ^m 21.5 ^s S 44 ^m 24 ^s . Chur: P ca. 42 ^m 00 ^s (Minutenlücke). Nachstoss des Bebens Nr. 96 aus Nord-Albanien.
98	" 25.	—	2.0	7	e 17 ^m 15 ^m 38 ^s e 18 ^m 48 ^s . Herd vermutlich auf dem Balkan.

Tabelle III. In der Schweiz 1926 registrierte Fernbeben.

Mitteleurop. Zeit; Mitternacht = 0^h.

Nr.	Datum	Epizentral- entfernung nach S-P	Ungefähre Dauer der Registr.	Phasen, Bemerkungen
	1926	km	Std.	
1	Jan. 13.	1920	$\frac{1}{4}$	eP (Mainka) 2 ^h 50 ^m 55 ^s , eS 54 ^m 11 ^s . Kleinasien.
2	" 13.	1900	$\frac{1}{4}$	eP ca. 9 ^h 13 ^m (keine Minutenmarken), eS-eP = 3 ^m 14 ^s . Nachstoss von Nr. 1, Kleinasien (geschlossen aus dem Vergleich unserer Seismogramme).
3	" 18.	9080	1	iP 22 ^h 20 ^m 00 ^s , eS 30 ^m 15 ^s . Epizentrum nach Strasbourg: 0° S, 87° E v. Gr., Indischer Ozean, westlich von Sumatra.
4	" 25.	—	2	iP 1 ^h 55 ^m 44 ^s , iP' 58 ^m 21 ^s , daraus d = 15 600 km. Epizentrum nach Sydney (Riverview), Zi-hai-wei und Phü-lien: 10° S, 158.5° E v. Gr. Salomo-Inseln, Stiller Ozean.

Tabelle III (Fortsetzung).

Nr.	Datum	Epizentral- entfernung nach S-P	Ungefähre Dauer der Registr.	Phasen, Bemerkungen
	1926	km	Std.	
5	Jan. 26.	—	$\frac{1}{4}$	ePv 8 ^h 24 ^m 26 ^s , sehr schwache Registrierung. Epizentrum nach Wellington ca. 21° S, 169° E. Gr. Neu-Caledonien (16500 km von Zürich).
6	" 29.	—	$\frac{1}{20}$	ePv 4 ^h 47 ^m 44 ^s , sehr schwache Registrierung. Epizentrum nach Wellington 23° S, 169° E v. Gr. Neu-Caledonien (16700 km von Zürich).
7	Febr. 4.	—	—	iPv 7 ^h 56 ^m 24 ^s , die weitere Registrierung durch Bogenwechsel gestört. Epizentrum nach Kobe ca. 41,5° N, 141° E v. Gr. im östlichen Teil von Tsugaru Straits, Nord-Japan, gespürt (9000 km von Zürich).
8	" 7.	—	$\frac{1}{10}$	ePv 9 ^h 09 ^m 16 ^s , iPv (auffällig starker Einsatz), 09 ^m 19,8 ^s . Wahrscheinlich aus der Gegend der Antipoden und identisch mit einem von Wellington gemeldeten Beben mit Epizentrum in der Nähe von Neu-Caledonien.
9	" 8.	9000	$1\frac{3}{4}$	iP 16 ^h 30 ^m 46 ^s , iS 40 ^m 57 ^s . Epizentrum nach amerikanischen Stationen Mittelamerika (Costa Rica oder Nicaragua).
10	" 8.	—	$\frac{1}{15}$	iPv 18 ^h 44 ^m 00 ^s , zweifelhaft, ob Fernbeben.
11	" 9.	8400	$\frac{1}{4}$	eP 1 ^h 36 ^m 58 ^s , iS 46 ^m 38 ^s , iPS 47 ^m 36 ^s . Epizentrum wahrscheinlich Amerika, doch aus den Angaben unserer Korrespondenten nicht näher bestimmbar.
12	" 13.	—	$\frac{1}{4}$	eN 10 ^h 28 ^m 09 ^s , schwaches Fernbeben ohne sicher erkennbare Phase. Herd unbekannt.
13	" 15.	9300	1	iP 4 ^h 12 ^m 31 ^s , iS 22 ^m 56 ^s . Epizentrum nach St. Louis (U. S. A.) 13° N, 87° W v. Gr. Nicaragua.
14	" 26.	1210	$\frac{1}{4}$	iP 16 ^h 49 ^m 59 ^s , eS 52 ^m 08 ^s . Herd wahrscheinlich im Mittelmeer. In Thunis wurden Erdstösse verspürt.
15	" 26.	1280	$\frac{1}{4}$	eP 17 ^h 11 ^m 44 ^s , eS 14 ^m 00 ^s . Gleicher Herd wie Nr. 14.
16	" 28.	—	$\frac{1}{10}$	eP? 23 ^h 18 ^m 23 ^s . Der Anfang der Registrierung ist sehr schwach und unsicher. Nach A. Rey Pastor (Traits sismiques de la péninsule Ibérique, 1927) ist das makroseismische Epizentrum ca. 38,5° N, 8° W v. Gr. Evora, Portugal (1630 km von Zürich).
17	März 1.	2080	$\frac{1}{6}$	iP 21 ^h 06 ^m 11,7 ^s , iS 09 ^m 41,5 ^s . Zerstörendes Beben aus Kleinasien, makroseismisches Epizentrum ca. 38° N, 29° E v. Gr. (1930 km von Zürich).
18	" 7.	—	$\frac{1}{4}$	P ca. 21 ^h 46 ^m 25 ^s (Minutenlücke). Herd unbekannt, nach Toledo vermutlich Mittelamerika.
19	" 8.	—	$\frac{1}{10}$	iPv 21 ^h 34 ^m 03 ^s . Epizentrum nach Kobe ca. 42° N, 143° E v. Gr. Kap Erimo, Nord-Japan (9000 km von Zürich).
20	" 15.	—	$\frac{1}{10}$	iPv 3 ^h 43 ^m 52 ^s . Herd unbekannt.
21	" 16.	—	$\frac{1}{10}$	ePv 18 ^h 57 ^m 12 ^s . Unsicher, ob Fernbeben, vielleicht identisch mit dem aus Apia (Samoa) um 18 ^h 38 ^m 05 ^s gemeldeten, dort gespürten Erdstoss.
22	" 17.	—	1	ePv 13 ^h 05 ^m 52 ^s , kein S zu finden. Herd nach Meldungen aus Amerika, Mittelamerika oder Karibisches Meer.
23	" 18.	2160	1	iP 15 ^h 10 ^m 35,4 ^s , PP 10 ^m 48 ^s , eS 14 ^m 12 ^s , SS 14 ^m 44 ^s . Azimut E 23° S, Epizentrum nach Strasbourg ca. 36° N, 29° E v. Gr., Mittelmeer südlich von Kleinasien, zerstörende Wirkungen in Süd-Kleinasien und auf den Zykladen.
24	" 18.	2150	$\frac{1}{4}$	eP 18 ^h 57 ^m 15 ^s , eS 19 ^h 00 ^m 51 ^s . Nachstoss von Nr. 23 aus Kleinasien.
25	" 19.	—	$\frac{1}{4}$	ePv 0 ^h 32 ^m 44 ^s . Vielleicht Nachstoss von Nr. 23.
26	" 19.	2180	1	iP 1 ^h 32 ^m 51,3 ^s , eS 36 ^m 30 ^s . Nachstoss von Nr. 23 aus Kleinasien.
27	" 21.	—	4	iPv? 13 ^h 19 ^m 13,3 ^s . Auffallend starker Vertikalausschlag, vielleicht Beben aus der Gegend der Antipoden.
28	" 21.	—	$1\frac{1}{4}$	e ₁ 15 ^h 38 ^m 00 ^s , e 47 ^m 07 ^s . Epizentrum nach Wellington ca. 67° S, 47° W v. G. Antarktisches Meer, Nähe Grahamland (13600 km von Zürich). Darnach wäre e ₁ = P', e ₂ = ScPcS.
29	" 21.	5900 ?	$\frac{1}{4}$	eP 23 ^h 08 ^m 46 ^s , eS? 16 ^m 17 ^s . Herd unbekannt.
30	" 22.	—	$\frac{1}{4}$	iPv 17 ^h 32 ^m 33 ^s . Herd unbekannt, da die Angaben der Korrespondenten sich ganz widersprechen.
31	" 23.	2110 ?	$\frac{1}{4}$	eP 3 ^h 03 ^m 05 ^s , eS? 06 ^m 38 ^s . Vielleicht Nachstoss von Nr. 23 aus Kleinasien.
32	" 24.	2090	$\frac{1}{4}$	eP 8 ^h 08 ^m 54 ^s , eS 12 ^m 25 ^s . Wahrscheinlich Nachstoss von Nr. 23 aus Kleinasien.
33	" 27.	—	$1\frac{3}{4}$	ev 12 ^h 08 ^m 03 ^s . Epizentrum nach verschiedenen Nachrichten Gegend der Salomo-Inseln.
34	April 1.	8950	$\frac{1}{4}$	eP 17 ^h 15 ^m 53 ^s , iS 26 ^m 01 ^s . Kobe, Japan, meldet eine Distanz von 300 km.
35	" 6.	3230	$\frac{1}{2}$	eP ca. 0 ^h 35 ^m 18 ^s schwach, eS 40 ^m 17 ^s . Epizentrum nach Cartuja 42,1° N, 31,4° W v. Gr. Azoren, wo das beschädigende Wirkungen ausübte.
36	" 9.	—	$\frac{1}{6}$	eE 11 ^h 13 ^m 56 ^s . Fernbeben, Herd unbekannt.
37	" 12.	—	2	eP 9 ^h 51 ^m 42 ^s , eP' 54 ^m 33 ^s , daraus d = 15200 km. Epizentrum nach Wellington 11° S, 162° E v. Gr. Neu-Hebriden.
38	" 22.	2250 ?	$\frac{1}{4}$	eP 8 ^h 16 ^m 06 ^s , eS? 19 ^m 50 ^s . Vielleicht im Zusammenhang mit Pressemeldungen von Erdstössen nördlich vom Kaukasus.
39	" 23.	—	$\frac{1}{4}$	iv 2 ^h 39 ^m 27 ^s , eE 45 ^m 41 ^s . Herd unbekannt.
40	" 24.	—	$\frac{1}{4}$	iP? 1 ^h 27 ^m 16 ^s , i 29 ^m 22 ^s . Herd unbekannt.
41	" 28.	—	1	ePv 12 ^h 27 ^m 10 ^s , ev 31 ^m 06 ^s , iScPcS 37 ^m 35 ^s . Epizentrum nach La Plata in der Provinz Antofagasta, Chile (ca. 11200 km von Zürich).
42	Mai 10.	7590	$\frac{1}{4}$	iP 9 ^h 30 ^m 09 ^s , iS 39 ^m 08 ^s . Nach Sverdlowsk 27° N, 95° E v. Gr. Himalaya.
43	" 20.	—	$\frac{1}{4}$	ev 8 ^h 20 ^m 11 ^s . Nach Batavia Menado u. Sangi-Inseln. Celebes-Meer (ca. 11500 km v. Zürich).

Tabelle III (Fortsetzung).

Nr.	Datum	Epizentral- entfernung nach S-P	Ungefähre Dauer der Registr.	Phasen, Bemerkungen
	1926	km	Std.	
44	Mai 26.	9070	$\frac{3}{4}$	iP 20 ^h 57 ^m 22 ^s , eS 21 ^h 07 ^m 36 ^s . Azimut N 20° E. Nach Kobe Epizentrum beim Kap Erimo, Nord-Japan (9000 km von Zürich).
45	" 31.	—	$\frac{1}{10}$	e ca. 14 ^h 49 ^m 02 ^s (Minutenlücke). Nach Wellington SE von Madagaskar.
46	Juni 3.	—	$\frac{3}{4}$	ePv 6 ^h 06 ^m 25 ^s , e ₃ 09 ^m 05 ^s . Epizentr. nach Wellington ca. 16° S, 168° E v. Gr., Neu-Hebriden
47	" 5.	—	$\frac{1}{20}$	iv 10 ^h 22 ^m 02 ^s . Herd in Japan.
48	" 5.	9000	$\frac{3}{4}$	eP 21 ^h 02 ^m 51 ^s , eS 13 ^m 00 ^s . Epizentrum nach Denver: Küste von Nord-Californien (9000 km von Zürich).
49	" 10.	1310	$\frac{1}{4}$	eP 20 ^h 19 ^m 07 ^s , iS 21 ^m 26 ^s , i 22 ^m 59 ^s . Nach Belgrad gespürt in Jugoslawien.
50	" 16.	—	$\frac{1}{6}$	eP 4 ^h 14 ^m 13 ^s , iM 17 ^m 06 ^s . Nach Belgrad gespürt in Prisren, Jugoslawien.
51	" 20.	—	$\frac{1}{4}$	eP? ca. 8 ^h 09 ^m 00 ^s (Minutenlücke), i 18 ^m 58 ^s . Epizentrum nach Wellington 53° S, 34° W. Süd-Atlantischer Ozean.
52	" 22.	—	$\frac{1}{20}$	e _N 6 ^h 11 ^m 34 ^s . Vermutlich Anfang eines Fernbebens.
53	" 24.	—	$\frac{1}{4}$	e _N 22 ^h 35 ^m 01 ^s , i _N 41 ^m 36 ^s . Nach den Meldungen der ostasiatischen Stationen liegt der Herd im malayischen Archipel.
54	" 25.	—	$\frac{1}{4}$	ev 3 ^h 18 ^m 16 ^s , ev 22 ^m 38 ^s . Herd unbekannt.
55	" 26.	2040	1	iP 20 ^h 50 ^m 34.9 ^s , i 50 ^m 37.6 ^s , iS 54 ^m 02 ^s . Azimut E 32° S. Neuchâtel: iP 19 ^h 50 ^m 31.9 ^s . Zerstörendes Beben im südlichen Kleinasien und auf den Zykladen. Epizentrum aus den Angaben von Zürich ca. 35.5° N, 28° E v. Gr. Herd vermutlich identisch mit dem von Nr. 23 dieser Tabelle. Siehe auch Tab. I, Nr. 23.
56	" 26.	2020	$\frac{1}{4}$	eP 22 ^h 23 ^m 46 ^s , eS 27 ^m 11 ^s (beides auf Mainka). Nachstoss von Nr. 55 aus Kleinasien.
57	" 27.	—	$\frac{1}{10}$	e 19 ^h 20 ^m 32 ^s . Wien vermutet hier einen Nachstoss von Nr. 23 aus Kleinasien.
58	" 28.	9390	$\frac{1}{2}$	eP 4 ^h 36 ^m 34 ^s , iS 47 ^m 04 ^s . Epizentrum nach Batavia 0,8° S, 100,7° E v. Gr. (10000 km von Zürich), zerstörend auf Sumatra.
59	" 28.	8550 ?	$\frac{1}{2}$	eP? 7 ^h 29 ^m 30 ^s (durch Bogenwechsel gestört), eS 39 ^m 18 ^s . Epizentrum nach Batavia 0,4° S, 100,3° E v. Gr., zerstörend in Padang auf Sumatra.
60	" 29.	9150	$\frac{1}{2}$	iP 15 ^h 39 ^m 35 ^s , iPP 42 ^m 57 ^s , PPP 44 ^m 28 ^s , iS 49 ^m 53 ^s . Azimut N 36° E. Epizentrum nach Strasbourg 38° N, 123,5° E v. Gr. Gelbes Meer.
61	" 29.	—	$\frac{1}{10}$	e _N 0 ^h 54 ^m 08 ^s . Schwaches Fernbeben unbekannten Ursprungs.
62	" 30.	—	$\frac{3}{4}$	eP? ca. 23 ^h 54 ^m 20 ^s . Der Anfang dieser Registrierung ist durch das vorhergehende Beben, Tab. II, Nr. 53, verdeckt.
63	Juli 1.	9220	$\frac{2}{2}$	eP 15 ^h 22 ^m 19 ^s , eS 32 ^m 40 ^s . Epizentrum nach Batavia Benkoelen (10000 km von Zürich), zerstörend an der SW-Küste von Sumatra.
64	" 1.	9470 ?	1	eP? 21 ^h 43 ^m 01 ^s , eS? 53 ^m 35 ^s . Epizentrum nach Sucre 16° S, 88° W v. Gr., Stiller Ozean, westlich von Peru.

3. Statistische Bemerkungen und Besprechung einzelner Fälle.

Im Jahre 1926 wurden in der Schweiz im ganzen 43 Erdstösse verspürt. Sie verteilen sich auf die Monate wie folgt:

Januar	Februar	März	April	Mai	Juni	Juli	August	September	Oktober	November	Dezember
5	8	2	1	1	11	3	3	1	4	2	2

Es fielen 35 in die Zeit der Ruhe (20—8^h) und 8 in die Zeit der Tätigkeit (8—20^h). Von den 43 verspürten Erdstössen wurden 25 auf der Erdbebenwarte in Zürich, 6 auf dem Observatorium Neuchâtel und 3 auf der Erdbebenstation Chur registriert. 7 hatten ihren Herd ausserhalb der Schweiz, nämlich 3 am Kaiserstuhl (Breisgau) und je eines in Krain, im östlichen Mittelmeer, auf den normanischen Inseln und in Griechenland. Die Herddistanzen betrugen für diese Sonderfälle 105 km, 320 km, 2040 km, 780 km und 1660 km. Die drei letztgenannten Fälle sind besonders erwähnenswert, weil es eine Seltenheit ist, dass bei Beben aus so grossen Entfernungen makroseismische Wirkungen festgestellt werden können.

Das Beben von Eglisau vom 19. März bot Gelegenheit, durch persönliche Umfrage an Ort und Stelle ein genaueres Bild von seinen Wirkungen zu gewinnen. Es verursachte keine Beschädigungen, versetzte aber immerhin die Bevölkerung in Aufregung durch die heftige, ruckartige und vertikal erfolgende Bewegung, verbunden mit einem sehr deutlich vernehmbaren Donnerschlag. Das Gebiet der stärksten Erschütterung war die Gegend am Rhein von Eglisau an aufwärts bis Tössriedern. Erdbebenstösse aus Eglisau sind schon seit alten Zeiten bekannt. Aus dem Anfang des 18. Jahrhunderts erzählt man sich vom damaligen Landvogt Salomon Landolt in Eglisau folgendes: Wenn der Herr Landvogt einen Besuch hatte, der ihm lästig fiel, so ging er zu seinem Barometer, beklopfte es und meinte mit bedenklicher Miene, das Barometer gefiele ihm gar nicht, es sei wohl wieder ein Erdbeben im Anzug, womit er die Gäste zum sofortigen freiwilligen Rückzug veranlasste.

Der ebenfalls habituelle Herd am Sarnersee machte sich in zwei Stössen von gleicher Intensität (V) am 16. Juni und am 30. September bemerkbar. Das überraschend ähnliche Aussehen der Seismogramme liess uns den Herd des zweiten Stosses sofort am Sarnersee vermuten, was durch unsere telephonische Anfrage in Sarnen bestätigt wurde. Diese beiden Beben zeigten deutlich eine interessante Erscheinung, die schon in früheren Fällen bemerkt wurde, und die eindringlich zeigt, dass gute makroseismische Beobachtungen Resultate liefern können, welche vorläufig mit noch so guten Instrumenten nicht zu erreichen sind. Von dem mit dem Epizentrum zusammenhängenden makroseismischen Schüttergebiet vollkommen isoliert wurden die Stösse vom Sarnersee im Jura gespürt, nämlich am 16. Juni in Waldenburg (Baselland), Aarau, Baden und Schaffhausen, am 30. September in Solothurn und Brugg, was unzweifel-

haft zeigt, dass die Erdbebenwellen stärker absorbiert werden durch die Molasse des schweizerischen Mittellandes, als durch die Kalkschichten, welche die Wellen aus den Voralpen in den Jura leiten.

Das stärkste Beben schweizerischen Ursprungs ging am 15. Dezember vom Kanton Freiburg aus mit dem aus makroseismischen Angaben gut bestimmten Epizentrum in Le Mouret. Dort wurden einige Kamine herabgeworfen, doch beschränkte sich die maximale Intensität VII nur auf ein ganz kleines Gebiet.

In einem grossen Teil der Schweiz gespürt wurde das Beben vom Kaiserstuhl (Breisgau), das am Epizentrum den Grad VII bis VIII erreicht haben dürfte. Alle vier hier genannten Herde boten Gelegenheit festzustellen, dass die aus den P-Einsätzen des grossen Zürcher Seismographen allein bestimmten Azimute Fehler von höchstens 5 Grad aufwiesen.

Betrachtet man die Tabellen II und III der in Zürich registrierten Erdbeben, so fällt sofort auf, dass das Jahr 1926 seismisch sehr aktiv war. Mit dem gleichen Instrumentarium wurden nämlich in Zürich registriert:

im Jahre 1922	43 Nahebeben und 42 Fernbeben
" " 1923	42 " " 63 "
" " 1924	70 " " 56 "
" " 1925	43 " " 42 "
also durchschnittlich	
pro Jahr	50 " " 51 "
im Jahre 1926	
dagegen	98 " " 126 "

Es drängt sich der Wunsch auf, es bei einer solchen Feststellung nicht bewenden zu lassen, sondern zu versuchen, jedem Jahr (resp. jedem willkürlich gewählten Zeitabschnitt) eine Zahl zuzuordnen, welche man die seismische Aktivität des Erdballes nennen würde. Auch für einzelne Gebiete könnte man eine solche seismische Aktivität definieren, was tatsächlich schon durchgeführt wurde¹⁾. Eine einzelne Erdbebenstation, und sei sie noch so leistungsfähig, kann nicht den Anspruch erheben, ein zutreffendes Bild der seismischen Gesamt-Aktivität zu ergeben. Diese wird heutzutage wohl am ehesten dem „International-Seismological-Summary“ von H. H. Turner in Oxford zu entnehmen sein.

¹⁾ Conrad, V. Schwankungen der seismischen Aktivität in verschiedenen Faltungsgebieten. Mitteilungen der Erdbebenkommission. Neue Folge Nr. 63. Wien, 1926.

Trotzdem ist zu sagen, dass eine leistungsfähige Station ein in grossen Zügen zutreffendes Bild der seismischen Aktivität im Umkreise von ca. 10 000 km, also für die nähere Halbkugel der Erde, geben wird. Die seismische Aktivität wird eine Summe von Grössen sein, von denen jedes registrierte Beben einen Summanden liefert. Jeder Summand stellt das Gewicht des betreffenden Bebens dar. Das Gewicht wird eine Funktion der Herddistanz und der Intensität der Registrierung sein müssen, wobei man nach dem heutigen Stand der Seismologie mit ziemlicher Willkür verfahren kann, ohne zu einer offensichtlich unvernünftigen Definition zu gelangen. Eines ist aber klar: um die Aktivität der Halbkugel der Erde, in deren Mittelpunkt die Seismometerstation liegt, aus den Aufzeichnungen dieser einzigen Station vernünftig zu definieren, muss man den Nahebeben ein sehr kleines Gewicht beilegen. Für die vorliegende kleine Betrachtung geben wir jedem Nahebeben das Gewicht Null, jedem Fernbeben zwischen 1000 und 10 000 km das Gewicht 1 und jedem Beben aus grösserer Entfernung auch das Gewicht Null, d. h. als seismische Aktivität der uns zugekehrten Halbkugel definieren wir einfach die Anzahl aller in Zürich registrierten Beben aus 1000 bis 10 000 km Entfernung. Es sind im Jahre 1926 deren 106 (gegenüber durchschnittlich 51 Fernbeben überhaupt in den vorhergehenden vier Jahren). Bei dieser Definition der Aktivität ist also auf die Intensität der Beben keine Rücksicht genommen, dafür ist jeder bei uns registrierte Nachstoss eines Bebens mitgezählt, sodass den meisten stärkeren Beben dadurch grosse Gewichte zukommen, dass sie von Nachstössen begleitet sind. Das Jahr 1926 fällt nun nicht nur durch eine grosse Gesamtaktivität auf, sondern durch ein ausgeprägtes Maximum der Aktivität Ende Juni. Die durchschnittliche wöchentliche Aktivität betrug in den Jahren 1922—25 ca. ein Fernbeben, im Jahre 1926 ca. zwei, in den sieben Tagen vom 26. Juni bis 2. Juli 1926 wurden aber elf Fernbeben registriert und zwar:

- 3 zerstörende Beben aus Sumatra,
- 3 Beben, darunter ein zerstörendes, aus Kleinasien,

- 1 Beben aus dem Gelben Meer,
- 1 Beben aus Peru,
- 3 Fernbeben unbekannten Ursprungs.

Es hält schwer, in dieser Anhäufung von Beben nur einen Zufall zu sehen, vielmehr kann man sich des Eindrucks nicht erwehren, dass eine gemeinsame Ursache dieses gleichzeitige Krachen an den verschiedensten Stellen der Rinde unseres Planeten bewirkt habe.

Betrachten wir nun die in Zürich registrierten Nahebeben. Ihre Anzahl kann entsprechend den obigen Vorgehen für Fernbeben als seismische Aktivität in einem Umkreise von 1000 km um Zürich gelten. Auch hier wird Umgang genommen von einer direkten Berücksichtigung der Intensität der Beben und dafür jeder registrierte Nachstoss eines Bebens mitgezählt. Die durchschnittliche wöchentliche Aktivität von 1000 km betrug in den Jahren 1922—25 ca. ein Beben, im Jahre 1926 1,9 Beben. Auch hier ist ein ausgesprochenes Maximum der Aktivität zu verzeichnen, welches zeitlich mit dem Maximum der Fernbeben-Aktivität zusammenfällt, und zwar wurden in den sieben Tagen vom 26. Juni bis 2. Juli 1926 23 Nahebeben registriert, nämlich:

- 7 Stösse vom Kaiserstuhl (Breisgau),
- 9 Beben aus dem Appennin,
- 1 Beben aus Spanien,
- 6 Nahebeben unbekannten Ursprungs.

Damit ist unzweifelhaft ein Fall von Parallelismus zwischen der Weltaktivität unserer Halbkugel und der Aktivität unserer Umgebung festgestellt, den man nicht zufällig nennen wird. Die Durchsicht des Materials früherer Jahre ergibt deutlich, dass ein ausgesprochener Parallelismus im allgemeinen nicht behauptet werden kann, umso mehr ist der hier vorliegende Fall bemerkenswert, und er scheint mir zu zeigen, dass die gleiche Ursache, welche die grossen Weltbeben dieser kritischen Tage hervorrief, auch die vielen Nahebeben auslöste, die zur selben Zeit in Zürich registriert wurden.

Die in der Schweiz im Jahre 1926 verspürten Erdbeben.
